Continental Crankshaft, nickel-chromium-plated, is shown here. In CONTINENTAL AIRCRAFT ENGINE CO., Detroit, Mich., Center Engine this plate is not used in nickel alloy steel parts.

CONTINENTAL AIRCRAFT ENGINE

(A Continental Motors Product)

insures dependability with Nickel Alloy Steel Parts

The Continental aircraft engine embodies the well-known principles of efficient design characteristic of all the products of the Continental Motors Corporation, the largest exclusive engine manufacturers in the world. For 29 years Continental engines have held an enviable position in the automotive world. The same engineering skill and knowledge of materials have gone into the making of this airplane engine.

Trained Man Power

Los Angeles County Has

55 Airports and Landing Fields

21 Airplane Factories

20 Aircraft Motor Factories

An average of 385 days per

year with sunshine

An average wind velocity of

only 5 MPH

An average of 274 days per year

when the thermometer is warmer

above 50° and below 67°

Continental Open Shop labor

Abundant industrial power, nat-

ural gas and water, at low rates

Ideal living conditions

High working efficiency

Low building and maintenance

costs due to year-round

equable climate

CONCENTRATION of the aircraft industry in Los Angeles County, as the natural result of better flying conditions, has developed here an extensive guild of trained man power, skilled in every branch of aircraft production and operation.

Twenty-six or more aviation schools have an enrollment of over 1800 students in training and are constantly releasing qualified men for service.

Los Angeles County has more licensed pilots than any other county in the United States.

These important factors, supported by natural year-round climatic advantages, make Los Angeles County the preferred location in all America for the profitable manufacture of aircraft and airplane motors and parts.

**LOS ANGELES
COUNTY**

Write to Industrial Department, Los Angeles Chamber of Commerce, Room 2010, Main and Spring, regarding the advantages and the opportunities in Los Angeles County

The Aeronca C2 was designed by Jan A. Benoit, head Aeronautical Engineer of the U.S. Army Air Corps, performed the fastest in Germany and a talk under the direction of General D. H. Stone, whose presence has added greatly to the popularity of this plane at the St. Louis Show. Its low profile, its ease of control, its wide choice of color combinations, its extra ruggedness, its performance and dependability would attract a wide range of interest in any place on the earth today.

The Sensation of the St. Louis Show..

"There's the most phenomenal plane I've ever flown... why, it's simply too good to be true."

Scores of pilots have made this remark after their first flight in the Aeronca C2. And, then they go into experiences which would sound unbelievable to anyone who hasn't witnessed a demonstration.

But, why shouldn't they talk this way... especially if they're flying a great deal and in all kinds of shapes? What other airplane will jump into the air at 31 miles an hour... after a run of 75 feet or less? What other plane will climb at a 34 degree angle to nearly 1000 feet on 20 horsepower in the first minute? What other plane would make sharp banks and figure eights over hazy fields above the ground, with the banks behind the head if he didn't feel sure that the Aeronca was far ahead of all others in interest.

And, when it comes to landing a aircraft with safety? What—outside of a telephone—will glide 11 miles down a height of 10,000 feet with a dead stick? And, when it comes to landing a aircraft

with five hours training can dive the Aeronca down to 31 miles an hour and make it to the ground with the proficiency of a war air pilot.

It's useless to go into details about the remarkable performance of this plane because you won't believe until you've shown that, if you're at all interested in flying, you'll find that the Aeronca C2 is the answer to all your problems.

You can learn to fly in 3 hours or less. You can cut your training costs in half. You can operate it on two gallons of gasoline an hour. And, best of all, you can enjoy the sport of flying... the pleasure of infinite freedom and the thrill of winning, speed and speed... in a plane which is so much a part of yourself at the time that you absorb a confidence and feeling of security which is unparallelled.

In short, the Aeronca C2 is what the country has been waiting for... the first absolutely safe, practical and economical light airplane. Let us show you how easy, fast, safe and sure.

AERONAUTICAL CORPORATION OF AMERICA
LONDON, AIRPORT CINCINNATI, OHIO

You'll like these features offered by the WACO '165'

Appearance . . . Performance
. . . Stamina . . . Economy . . .
Typical WACO Value
.

YOU'LL like the WACO "165" from the first glimpse . . . its trim lines . . . its custom finish and wide choice of color combinations. You'll thrill to its easy take-off and quick climb . . . its effortless responsiveness to the controls . . . its arrow-like steadiness flying "hands off" . . . its typical WACO ability to get in and out of the smallest fields.

And you'll have absolute confidence in the proved design of the WACO "165" . . . its extra ruggedness of construction . . . its ability to withstand an extraordinary amount of abuse. You'll be pleased with the completeness of its equipment . . . such as Bendix brakes, compass, air speed indicator and dual controls. You'll be sold on its thoroughly practical performance . . . disposable load of 1,070 lbs. . . fuel economy . . . three-place arrangement . . . ample and convenient luggage compartment.

The "165" is a typical WACO value. Its moderate price is due to quantity production methods,

Approved Type Certificate No. 1107

and is a result of WACO'S widespread popularity. There are more WACOS in use than any other make of commercial aircraft in America.

We will gladly refer you to the nearest one of the nearly 300 WACO dealers, that you may prove to yourself at first hand the merits of the WACO "165." And . . . today . . . write for your copy of the new booklet which gives full details and specifications of this unusual airplane. The WACO Aircraft Company, Troy, Ohio.

"Ask any Pilot"

Kittyhawk Specifications:

Engine—Kaiser E-5	100 h. p.
Approved Type Certificate No.	146
Length overall	22 ft. 11 in.
Height overall	8 ft. 8 in.
Span both wings	35 ft.
Chord both wings	4 ft. 6 in.
Wing area	233.4 sq. ft.
Weight empty	1127 lbs.
Useful load	760 lbs.
High speed	170 m. p. h.
Cruising speed	90 m. p. h.
Landing speed	35 m. p. h.
Climb	1250 ft. p. m.

Also Approved Type Certificate as a Seaplane.

Some planes are built for speed

But to gain superiority in either speed or stunt performance, a plane must sacrifice safe flying qualities. The Kittyhawk will travel 170 miles per hour... it will out-perform most planes in its class... but we have not attempted to develop these features at the expense of safe flying.

The Kittyhawk is a light, three-place biplane... built for training, commercial and private use. With a landing speed of 35 miles per hour... with a wheel tread of 7 ft. 2 in. an inexperienced pilot can get into or out of small rough fields with a greater degree of safety.

Try to spin the Kittyhawk... a few skilled pilots have been able to hold it in a spin for three or four turns... not more. Certainly, this is a feature of safety which few planes can duplicate.

And what an engine!

With the time tested and proven design of the 7 Cylinder Warner Junior to start with, and the benefit of all the knowledge and experience gained in the production and actual performance of that now famous model, no wonder we can be proud of this newest Warner achievement.

90% interchangeability of parts with the 7 Cylinder Model, assures that in this new 5 Cylinder Warner Junior all of the excellent and proven features of the 7 have been retained.

Nothing untried, nothing experimental, finds a place in this Junior Model—only those proven features of design

and construction that have enabled Warner engines during the last two years to win all closed course races and all Cross Country Drives in their power class at the National Air Races.

For use in the light aeroplanes that have recently come into such desired popularity, this 5 H. P. Warner Junior embodies all of the qualities heretofore obtainable only in much larger engines.

Produced in one of the finest and most modern of aircraft plants in the country and with unexcelled production facilities, we are able to offer this new Warner Junior at a very moderate price consistent with the Warner quality that is built and designed into it.

NEW COWLING and MANIFOLD for WASP JUNIOR

A new exhaust collector, nose
cowling and pre-heater combination
is now ready for use on the
"Wasp Junior" 300 H. P. engine,
insuring proper engine operation
under all weather conditions.

All parts of the cowling and
collector are accessible, and engine
and accessories may readily
be reached. Individual parts may
be replaced without disturbing
the unit as a whole. Further, the
cowling is so constructed that the
airplane designers completely

hampered in providing for its use.
The collector ring is mounted on
the rear of the engine. It is elliptical
in section and carries a single
outlet delivering exhaust gases
either to a tail pipe or directly to
the atmosphere. Due to adequate
ribbing and solid mounting, the
cowling is extremely rigid. Shutters
are adjustable and a convenient
control is provided.

The fanning and hot air stove
serve the dual purpose of decreasing
engine drag and the

provision of ample quantities of
heated air for the carburetor
under the coldest operating conditions.
This new unit has been
designed for durability and long
service. Materials and workmanship
conform to the rigid standards
of Pratt & Whitney quality.

**"NO NEED
TO THROW THAT
OIL AWAY**

..... it's
Quaker State!"

Quaker State Aero Oil will still be so good that it is needless to change it, wasteful to throw it away.

Why this oil just gives at a grind that would wilt an ordinary oil—for there's an extra quart of sweet-running, friction-soothing lubrication in every gallon of it—a quart more than you get in the gallon of ordinary oil. And that's due to Quaker State's method of refining.

Ordinary refining leaves in every gallon of oil, a quart or more of material that has little or no value as a lubricant to your motor—just a quart of waste, that's about all you can call it.

But Quaker State Aero Oil is not re-

fined in the ordinary way. It is super-refined—carried a step further. This extra step removes the quart of waste that ordinary refining leaves in. In its place you get a quart of the finest lubricant. What you actually get is an extra quart in every gallon of Quaker State Aero Oil!

Take it? Why then oil will stand up and fight long after the ordinary oil would be cooked out—for it comes from fighting stock. It's made from 100% pure Pennsylvania Grade Crude Oil, and there's no better—it's the very finest crude oil the world produces.

Ask for Quaker State Aero Oil at your airport. Try it out on your next haul. It's remarkable how it holds its body. It will stand more heat than an ordinary oil will live through—and it will stand up and keep your motor purring its prettiest. Try it!

Get that extra quart in every gallon of

QUAKER STATE AERO OIL

The
BATTLE FLEET..
CORSAIRS
are always with it

WHEN the commanding officer swings a modern battle fleet into action he must have accurate, up-to-the-minute information.

A generation ago naval commanders had scant means of getting this information. Today they get it from the air.

That is why the aircraft carrier, with their squadrons of Corsair observation airplanes on board, are so important an adjunct to our battle fleets. And the carrier planes are

supplemented by Corsairs on each battleship and cruiser.

Wear and tear on planes with a battle fleet cannot be compared with ordinary service flying. As a biplane, quick take-offs must be made from the carrier's deck. As monoplane they are catapulted from the decks of the battleships and cruisers. When the desired information has been secured through air observation, landings must be made into arresting gear, or on the water along-

side the mother ship. It requires an airplane of exceptional sturdiness—of rugged dependability and maneuverability—to stand the puff.

These exacting qualities have been built into the Corsairs. They are the qualities that have made the Corsair an outstanding contribution to American aircraft design. CHANCE VUGHT CORPORATION, Long Island City, New York. Division of United Aircraft & Transport Corporation.

A PILOT'S VIEWPOINT.....

"When the 'prop' there is, first is doing its steady turn, and the motor is giving that smooth, thrillsome draw—then I can rest easily in the seat, confident all's well in the motor. But it takes a real lubricant to get that security, on all that measures far above the engine. Skelly Airplane Oil is that lubricant."

"It's right at the take-off when I know whether Skelly gasoline is the tanks. It's the rush of power that leaves the earth behind . . . and after that, constant unwavering power for speed, or altitude, or whatever we want. Tried out again and again, in all types of aircraft and under all conditions—Skelly Aerodynamic is that gasoline."

TRAVEL AIR SAVES TIME

for the world's largest makers of time-saving tools

INDUSTRY sees a new pace. It was therefore a natural development that Black & Decker, the world's largest makers of portable electric tools, chose the Travel Air Six-place Cabin Monoplane to bring their executive sales territories into closely supervised unity.

In January, the Black & Decker Travel Air was sent on a 38-day tour through eight southeastern states. District managers accompanied the salesmen-pilot through each territory. Important sales and a new assurance of service were the result.

Time-saving! Golden words to great business organizations. Sturdy Travel Air is designed and engineered by the world's oldest and largest airplane manufacturing organization. Reliable! Wind and weather hold no difficulties for Travel Air steadiness and in-

terprise maneuverability. Fast! Wright-powered with 300 h. p. Whirlwind engine; speed up to 135 m. p. h. A 430 h. p. engine is available in a more luxurious model. Comfortable! The roomy, 6-chair cabin can be fitted with office furnishings to suit the purchaser. Service! A countrywide network of Curtiss-Wright bases assured prompt service to Travel Air users whenever they fly.

Low Operating Cost: Actual figures, surprisingly low, on operating cost will be gladly furnished to interested executives and concerns. Full details of Travel Air construction and performance can be had by addressing Dept. T-73.

TRAVEL AIR COMPANY
Division of CURTISS-WRIGHT
Sales Office: 27 West 57th Street, New York

The Travel Air Cabin Monoplane of Black & Decker Mfg. Co. is rapidly used by its air-minded officials. Here are Vice President A. G. Decker and President S. D. Black sitting with one of their many interesting flight suit F. E. Johnson, Salesman-Pilot.

TRAVEL AIR

A PLANE FOR EVERY PURPOSE

AVIATION

THE OLDEST AMERICAN AERONAUTICAL MAGAZINE

A McGRAW-HILL PUBLICATION • ESTABLISHED 1878

EDWARD F. WARNER, Editor

VOLUME 11 • March 1, 1930 • NUMBER 3

Tell the World

THREE MONTHS AGO it cost as a general rule something between ten and fifteen cents a mile to travel by air. Now the rates range from five to eight cents, a flat fifty per cent drop between the middle of the football season and Lincoln's birthday. Why the cut? What benefit was it designed to render to the operating companies? Has it done it?

In the turbulent days of last September there was frequent expression of the comforting view that economy was not an objective with travelers by air, that they wanted speed and luxury and would pay any price to secure them; that air transport was immune from any economic competition with organized means of travel upon the surface of the earth.

The holders of that view cooled off under the chilling blasts of traffic analysis. It was given fact that passengers were not traveling by air in sufficient numbers to carry the unescapable overhead of the operating companies. There have been many explanations, complete or partial, of the comparative failure of the general public to patronize the services provided, but we have settled down to universal agreement that the root of air transportation is one management factor, and an important one.

To agree upon the cause was to apply the remedy. Rates went too high and traffic was inadequate. Rates were cut markedly and to some extent, without regard to the possibility of making the new figures balance with present operating costs. Traffic improved, but it should and must improve much more. In our judgment the full possibilities of the rate cut have not by any means been realized, because, in our judgment, the fact of the cut has not yet penetrated the public consciousness.

To us who are professionally engaged in aviation it is a commonplace. It has been so much an outstanding circumstance of the winter season that it is hard for us to

believe that anyone could have overlooked it, but make the trial for yourself. Can yourself in the role of the inquiring reporter. Go forth and stand upon a street corner and ask the first ten men that come along how they think the cost of a trip by air compares with that of the same journey by rail. We shall be greatly surprised if seven of the ten do not reply to the effect that air travel is reserved for millionaires.

The newspapers have given some publicity to reduction in fare at the time when they have been unseasoned, but a story can only be news once, and having once marched across the page it fades from the memory of man. It takes more than one corrective note to obliterate impressions that have, like the general impression of the confidence of air transport, had years to take root.

The economic factor in traffic development is only one of several that have to be reckoned with. There are many journeys that will not be made by air under present conditions, however low the rates may be set; but if rates are to be whittled away at their base, at least the operators should get the full benefit of their financial savings. They can only do so by the most persistent advertising of every kind—newspaper, direct mail, word of mouth. The personnel of every connection that needs to be a city served by air lines ought to be indoctrinated, as some of them already have been, by the morning companies that may hope for the patronage of their members. In their publicity work the representatives of the air lines should make it their first business to call attention to lowered cost, the one of their attractions of which the public knows least. Every speech that is made in the interest of air transport, for the next three months at least, ought to be focused upon the subject of low fares as the point of greatest interest to the public.

Keep at it endlessly, and the idea will at last

ank burst. Means of travel are commonly selected in haste, and almost instinctively, without pause for reflection. To get the relative cheapness of air transport so impressed upon the average business man that he will never overlook it when a chance has to be made still needs long and persistent hammering.

//

Parasites on Aviation

ALTHOUGH the stock market's debacle has resulted to some extent the flood of aeronautical security offerings and has reduced the usefulness of prospectus so that they are now more likely to start out in quest of \$50,000 rather than \$10,000,000, it has not exterminated the rise of fraudulent financing. Some of them have gone temporarily under ground. Some have changed the form of presentation of their plans to give them a more altruistic aspect. Some have devised various plausible schemes for persuading the investor that he is being vouchsafed a sacred privilege by being permitted to have over his money, and that he is being admitted to an elite group. So crude and naive is the presentation that some of these make for their projects that it is difficult to imagine their taking in anyone who has had the intelligence to accumulate any money for investment, but the sad record of history proves that nothing is so crude or so vaguely honest that it cannot gather in a respectable coterie of victims.

We have a circular before us as we write. It describes a new kind of "airship" (sic), although apparently left by the language of gas, which is the characteristic feature of all airships as correctly defined, plays no part in this design. "The type of plane now in use will never be a commercial success," proclaims the prospectus, "because of—the absence or lack of land-like features. It is a known and absolute fact that the structure of the present type of plane cannot withstand the tremendous pressure created by air pockets, which have caused many disastrous crashes and have taken a toll of human lives." In this novel concept, on the other hand, "the type of rubber used" (which a perspective drawing shows to have the general appearance of a pail-like fan) "eliminates the danger of air pockets created by the magnification of rubber and elastomer now used on other planes."

The last that can be said for the editors of those glittering phrases is that they are totally ignorant of the fundamentals of aeronautical science and of all other sciences. One might, without undue lack of charity, say of them something far worse than that.

Unwisely, they do not stand alone. We have recently fallen foul for the third or fourth time in as many years of a gentleman who has some good ideas for plane airplanes. Periodically he appears with a fuselage of tinplate and persuasively craves a little money to

start construction. Periodically he fades from view, slowly to break out again in a new plane, demonstrating anew the same old bit of misleading publicity about a project already in its essentials at least ten years old and upon which no perceptible progress has been made in that interval. At last, the promoter is suddenly over-optimistic about his own prospects. At worst, again, his activities bear a far spherer interpretation.

The Post Office Department has given attention to some of these gaudy, and the Better Business Bureau has done their best to make life miserable for others, but it is not always easy for those without aeronautical experience to be sure of just what does constitute a manifest impossibility or a proven false fraud in an aeronautical project. They need help from the experts. The tribulations of aeronautical securities attached to perfectly sound manufacturing or operating enterprises during the past few months make it doubly important that the aircraft industry should be more thorough and above suspicion. We must clean house from within. We must not only bar the gate of our own association against suspicious intruders, but we must choose them from the neighborhood. The aircraft industry ought to take for itself the air of being so respectable as to shun the odor of unsavory men who attach themselves to it,—but thus its members must make sure that none of the intruders are parasitic, saving away that public confidence that is the root of their future prosperity.

//

Liquidating Overproduction

SOMEONE has said that the way to solve half of a complicated task is with both hands. It does no good to vacillate in the starting of an unpleasant duty, which must eventually be performed. Any unpleasant, but reasonable, is the duty that faces those units in the aircraft industry which must unload thousands of a rather considerable number of airplanes now in storage as a result of overproduction during 1939. Factories, distributors, and in some cases finance companies are holding large numbers of aircraft which must be disposed of in one way or another before the industry can return to a normal basis. Every day in storage decreases the intrinsic worth of the airplane waiting to be sold, both on account of actual depreciation and because of the obsolescing process resulting from the passage of time and the introduction of new and improved models of airplanes. A still more important, though less tangible, factor is that aircraft frozen in warehouse act as a direct drag to progress of the industry. As news of the fact that there are many unsold planes on hand leads to the possible prospects for purchase of new equipment will certainly feel that aviation is a losing business and that tomorrow plans for entering it, either as a commercial or

private flyer, but better be postponed until the storm blows over. On the other hand, if those stored planes be cleaned from the docks at any price which can be obtained they will be in service, more people will be flying and will be coaxed to flying, the old equipment will be worn out the sooner, and increase in the number of aircraft purchases will be greatly accelerated.

Naturally many centers of aircraft equipment will argue that if they cannot obtain a reasonable price for their merchandise they will be lessened ruined. On the other hand it is more intelligent to save something from the wreckage of a production program gone wrong than to sit by and hope for future salvation both the result that a total loss results. If all concerns holding large unsold stocks of aircraft will liquidate, at whatever price may be necessary, the money realized will make it possible for the stronger ones to continue business as a more intelligently organized program. The weaker ones may hope to escape enough from the debacle to return in good order.

One last stand can clearly, and that is that our present unsold equipment consists, in large part, of first class airplanes which will give good account of themselves if placed in service. The quicker they are put to use the quicker they will be worn out and make way for the normal future production. At the same time these planes will be increasing the total amount of flying, training new pilots, and bringing new converts and new prospects to the builders of newer equipment.

Such unloading of frozen stock will hurt those who must sell at a sacrifice, and will temporarily hurt the manufacturers who have kept pace with the market and now have no stock overhand.

Many have hoped that this "unloading" process might be done in foreign markets, thus save the home situation while building our trade abroad. The export market is, however, still a somewhat unknown and a limited quantity. While making every effort to develop it, we should also clean house at home.

In spite of the recent setback within the industry the business of flying is steadily growing in popularity. We must foster and nurture the growth. Unsold stock is a fostering force in the business of the industry, and will hamper the return of healthy business conditions until banded. Decisive and immediate action is needed.

//

The New Men in the Industry

DURING the recent rapid expansion of the aviation industry it was necessary to recruit engineering and drafting personnel from other industries, as well as from the ranks of recent graduates in mechanical, civil, and electrical engineering. By proper distribution of the newcomers under the direct supervision of experienced

aeronautical engineers and draftsmen, technical work was carried on in a very commendable manner. By proper sub-division of work, and specification of the aeronautical services under experienced supervisors, full advantage was taken of their fundamentally sound previous engineering and drafting training.

Thus an immediate and extraordinary demand was successfully met in a logical manner. It is hoped these men, initially drafted for aeronautical service, will remain, to the mutual advantage of the industry and themselves. However, the frenzied days of last summer are over and the industry is pushing ahead on a quieter and sounder basis. Control lines are being tightened, and increased refinement of design detail is the new order of the day.

This requires a far more intimate understanding of aeronautical technical matters on the part of every individual associated with the engineering of a plane design. Only by the intelligent contribution of the intensive and design sense of every one engaged in engineering work can the new objective be attained. It is a time for these relatively new recruits to aviation engineering to take stock of themselves, and acquire a more intimate knowledge of fundamental aeronautical design precepts if their own future personal success is to be assured.

It is believed that most of these men are willing,—that they will take any reasonable and available steps to better equip themselves for success in aeronautical engineering and drafting. Unfortunately, a survey of the possibilities for further education shows that woefully weak. True, there are some educational opportunities available for the prospective aviation man—the pilot, mechanic, etc.—in the excellent aviation schools recently well distributed about the country. There is a wealth of opportunity for the versatile man who seeks general elementary aeronautical knowledge, but the man under discussion here for more advanced technical education.

True, they have available post-graduate courses in the universities with aeronautical departments, but so in most instances they must be self-supporting that it is not a practical solution. Where the particular aviation concern for which they are now working is located in centers close to these aviation centers, satisfactory arrangements for continuing courses could undoubtedly be made. Unfortunately, the aviation industry is widely scattered and so most instances is relatively small communities far removed from such opportunities.

What is believed to be very badly needed is an authoritative correspondence course in airplane design under the auspices of one of the recognized universities teaching aeronautical engineering. Such a course should be based on a prerequisite of an engineering degree or its equivalent in practical experience, and should emphasize the application of aerodynamics and structural analysis to the design of a plane. That such a course would be enthusiastically welcomed, and prove a distinct contribution to the aeronautical industry, is fairly believed.

THE *St. Louis* SHOW

Second International Aeronautical Exposition is Colorful But Reveals Few New Designs

By JAMES P. WINES

THE SECOND International Aeronautical Exposition, held late last month at the Arena in St. Louis, without question was the most colorful aircraft show that has ever been conducted. The interior of the exhibition hall was lavishly decorated and that combined with the brilliant lines of the planes exhibited,

as well as the colors used to decorate the booths of engine and accessories manufacturers, made the show what it was.

From the technical angle there was little that was new. It is true that certain refinements in design have been effected, but for the most part there were very few structural changes in the new models over those exhibited at previous showings. On the other hand, the planes revealed the fact that the manufacturers are making a definite attempt to beautify products. The makers

of airplanes are now reaching out to the public in general, which includes a large class of potential buyers not yet educated to the technical side of aviation.

Striking color combinations such as orange and black, predominated in the exterior finishes. The interior of the main planes, a little more quiet for the most part, were also designed to catch the eye. Colored leather, tapestries, plush and figured velvets are now finding a place in the modern plane. In fact, many of the color planes now rival the late views of the most expensive automobiles. Comfort, too, is being emphasized. Seats have been made more comfortable; their arrangement has been improved, and more and more manufacturers are discarding the old and uncomfortable rubber shock cord in favor of hydraulic or other shock absorbing units.

Yet the show was a disappointment. The Arena, where the exhibition was housed, was constructed at the home of a dairy show, and frankly it could have served for that thus far for the purpose of housing an aeronautical exhibit. It consists of three buildings. The central structure is an arena, with a turbaric ring and the galleries completely enclosing it, while on either side is a large box-like structure. Ordinarily the three buildings are not connected, but enclosed plaster-board passageways were constructed in preparation for the aircraft show.

THE ACCESSIBILITY to the east and west of the Arena, which are known as buildings "A" and "B" respectively, it is understood, were used to house cattle during the dairy show. In fact, the concrete floors are said to have been laid there just before the aeronautical exposition was held. Formerly the flooring was dirt. However, the arena remained covered with its layer of turbaric, and there was noisiness in the passageway between the buildings. Of course that may have been an attempt to create proper atmosphere. The doors and trouser cuffs of a person who walked through the exhibit were sure to look as though he had spent a day at a dusty airport.

The floor of the exhibition hall totaled some \$60,000 so it. A complete dress of the building, saving and fraying at one end, would give the average visitor all the comfort that he wanted in one evening. But the only entrance where tickets were sold was at the front door

Above is revealing first part of the International exhibit. Below, the Southwest exhibit at the North Atlantic Fair.

of the outer structure. There were other entrances at the rear building "B" for those who parked their cars in the space provided there for that purpose, but there was no ticket office, which made it necessary for everyone except the exhibitors to utilize the front door. Even making use of those entrances, however, necessitated walking. No vehicles were allowed in front of the structure. If one drove up in a taxicab, he left it at the west of the building and walked to the entrance. If he drove in his own car, he parked it in the nearest parking space and walked still farther.

Again, the visitor had three alternatives. He could go directly to the turbaric ring, and, accidentally, if set down to the floor it was necessary to descend a flight of stairs he might turn to the right, walk half way around the arena to the passageway leading to buildings "B," or he might go to the left, eventually arriving at building "A." No matter what he did, he stood excellent chance of losing himself in the maze of corridors. The passageway rooms, it might be added, are on the mezzanine floor.

For a crowd, a boxing match, or anything of the sort where the spectators remain seated all evening, the arena is doubtless well planned, but it is a poor place for an aircraft show.

Building "B" was the most attractively decorated and arranged of the three. There were three floor plans in the structure by actual count thus there were in building "A" but they were of similar type. As a result,

A view of the St. Louis Arena. A part of the Southwest exhibit is in the foreground.

one obtained an impression of spaciousness entirely lacking in the other structure. The exhibits at this exposition showed the result of the many changes that have taken place in the last few months. In many instances, space was taken under the nose of the holding compartments, and several makes of planes were displayed in the nose booth. That fact was detrimental to the appearance of building "A." The new Curtiss-Wright exhibit was located in that structure, and of course the 35-passenger Keystone-Loring "Patriot" and the 18-passenger Curtiss "Condor" were included in the display. The entrance was of such size that its wing almost scraped the cross-aisle piers, which contained the seating and supported the lighting fixtures of the building while the Curtiss had to be set up with the wings missing between the center. The largest plane in building "B" was a Ford tri-motor.

THE EXHIBIT of Detroit Aircraft Corporation was the largest in "B." Seven of the 25 planes displayed in the building were on exhibition in the space allotted to the Detroit concern. These were the new Lockheed "Sensen," the Lockheed "Executive," Parks P-1, Parks P-2, the Eastman "Flying Yacht," the Ryan B-5 and the smaller Ryan C-1. The latter is a new "Whirlwind-Seven" powered, four-place monoplane which was unveiled the first night of the show. After the manner of most of the new planes, the wing was painted a brilliant orange while the fuselage was done in tan and cream color. Incidentally, the Ryan C-1, or "Patriot," as it was called by some of the representatives of the company, was one of the growing number of four-seater planes that made their appearance at the show.

The cabin interior of the new Ryan is done in velour. The top is plain brown, while figured material is used for the side walls and the seats. The rear seats, which are staggered, are the arm chair type and may be tilted backward. The pilot's seat is a bucket affair. The one advantage is in the folding variety and device for all the world like one of the front seats that may be found in almost any two-door sedan. However, it is possible to place the back of the seat in a horizontal position by moving it backward as well as forward. The feature of this arrangement, however, is the fact that the folding front seat becomes a bed when used in conjunction with the rear seat on the right side.

The floor space is of the ordinary automobile variety. The housing, again, is of the automobile type. A cloth pocket on the door is exactly what might be found in an automobile. The wooden and the leather panels show striking similarity to the cloth and leather panels of the modern motor car. The curtains over the windows and

the dome light are like those to be found in the sedan.

The interior appointments of the new Ryan have been described somewhat in detail. Naturally, the interior dimensions of the other planes on display at the show differed slightly. Some monoplanes had wider cabin balance, some large patterns. Leather and leather in combination with fabric were to be found. Structured members entering the cabin were painted or covered with fabric. The latter, it might be said, seems to be the better way of handling these necessary coves. Without straps to carry all interior members were used to finish the window ledges. In a word, practically every cove without exception showed the influence of the closed car.

Of all the planes exhibited by Detroit Aircraft Corporation, the new Lockheed "Sensen" attracted perhaps the most attention. This was due to its striking appearance, and the fact that the above model was a duplicate of the one now owned by Colonel Lindbergh. The Sensen is a low-wing monoplane, powered with the Pratt & Whitney "Wasp" engine and equipped with the N.A.C.A. winging, and it looks like a West point cadet's cadet to the effect. The wing and the tail surface of the one on exhibit were painted orange while the fuselage and landing gear were black.

A missing grid protection by Gliders, Inc., also attracted much attention, as did a canopy section of the cove of a Lockheed "Viper."

CORPUS CHRISTI had a booth about one-half the size of that occupied by the Detroit concern. In that space three models of Stinson monoplanes were shown. There was very little discussion. The Detroit company had plans, which formed the entrance to its space, painted in checkerboard fashion in black and orange to look like plywood. Smaller planes, joined by chains which were painted orange, marked the boundaries of the display and carried out the color scheme. It was really very effective. On the other hand, the simplicity of the Corp. Christy exhibit made it almost if not equally as effective. A green floor cloth was used with standard carrying a red plush colored rope placed around the outer edges. The three planes—a Wasp, a "Whirlwind-Seven," and a Lycoming powered Stinson Detour—were placed in the booth in an odd way.

Other planes on display in building "B" included a Command-air biplane in a biplane; two St. Louis Cardinals, the Pratt & Whitney powered Ford transport, an American-Savo-Marchetti amphibian, powered with a Kinner engine, a Lincoln PT, the New Standard, four American biplanes, one powered with a new 350-hp. Kinner Swoosh-engine; two Davis powered monoplanes, two Bering NB-3's, two Spartan biplanes;

The Curtiss-Wright exhibit, showing the Keystone-Condor set up in an artificial pond.

a Fokker Super-Universal; a Fiat biplane; a Whitley Avon, and a Biplane monoplanes.

The Nicholas-Bearley exhibit which featured the Bering NB-3 is worthy of comment. The ceiling of buildings "A" and "B" were so low, that it was impossible to hang any of the planes exhibited in flight position. However, there is charge of arranging the Nicholas-Bearley booth, it was difficult to do. The tail of one of the two Bering NB-3s on display was heated up, so that the plane with the wheels touching the ground looked as though it were in a dive. To make the picture more realistic, two clothes hampers acted as flying tops were used in the forward cockpit to represent passengers, and another dummy occupied the pilot's seat.

The landmark ring of the Arenas proper seemed to be chiefly a connecting link between the two buildings to the east and west. Seventeen planes were exhibited there but several of them were shown in the other exhibition halls. Curtiss-Wright was the only exhibitor in the Arenas to arrange and display. It had about a quarter of the entire space in the ring, and decorated the area to look as much as possible like a garden. The landmark was covered with imitation grass, with weeds of various kinds in various of the corners. A small bushy bushy covered the booth from the circus atmosphere of the rest of the ring. Four planes were shown. These were the Curtiss "Tanager," which was the \$300,000 Gipsyliner airplane, the Curtiss "Whirlwind," the Travel Air Mystery plane, and the Keystone-Loring "Condor" amphibian. The latter attracted perhaps the most attention, since it was about as a water-filled concrete basin. The "Whirlwind" also proved quite an attraction.

The remaining thirteen planes in the Arenas were a Fordell KR-1, a Nohok low-wing monoplanes powered with a Kinner engine, a St. Louis Cardinals, the Bell Aircraft "Spokane Sun-God," a Bering NB-3 mounted on skis, a Lycoming Stinson the "Baby Ace" a new single-engine, externally fixed cabin monoplane powered with a three-cylinder Siskely or cooled engine, a Wasp straight wing model, a General Aviation Corporation "Aviator," an American Eagle cabin monoplane; the Armona C-2, the light plane recently placed on the market by Aero-Astronaut Corporation of America; the Great Lakes Sport Trainer, a Command-air biplane equipped with a Kinner engine and a Wright Whirlwind-Seven powered Wasp Taperwing. The Command-air and the Taperwing were suspended in flight position by cables dropped down from the roof.

At one side of the Arenas stage was constructed for the performance of the "Wings of 1930," a musical revue-entertainment. Held in conjunction with the show, on which the curtain was rung up nightly at 10 o'clock.

BY FAR the largest single exhibit in building "A" is in the Arenas was that of the Curtiss-Wright corporation. In addition to displays of the Curtiss-Wright line of airplanes the company exhibited 11 planes. These were the Patricia, Keystone-Loring "Aviator," the Corning three-place Travel Air biplane, the six-place Travel Air cabin monoplane powered with a Wright Whirlwind. Nine—the Curtiss "Carnegie Pigon," a "Blind" equipped with a Kinner engine, which were painted green and silver to match the color scheme of the fuselage and wings, a "Blind" biplane with pyro engines over each cockpit, and three models of Curtiss "Robins." One Robin was of the well-known three-place type powered with a CX-3 engine. The second was also one

An exhibit of aircraft engines, equipment manufactured by the International Motor Co.

of the three-place planes but it was powered with a Wright "Whirlwind" engine and equipped with a tail wheel and landing. The third product of the Curtiss-Wright corporation was a four-place biplane, a new four-place Robin. The plane was previously the same as the three-place model, except for the fact that the fuselage had been widened by four inches to allow installation of a double seat in front instead of single made pilot's seat.

Other planes exhibited in building "A" included two Biplanes "Pioneers," one equipped with a Kinner engine, the Ford tri-engine de luxe club plane, two Wasp one powered with a Kinner and the other with a Whirlwind-Seven engine; a Fiat biplane displayed on a revolving stand in the center of the United Aviation Show exhibit; a new Leont off dashdown there

The display of the Illinois Aircraft Corp. The new four-seater "Wings" is shown in the left.

plane (Laplace); an Island Sport plane; the Brewster Knicker, two Cessna cubic monoplane; the Verville "Aerocub"; a Fairchild KR 21; a Fairchild KR 34, the model 71 Fairchild monoplane; the Fairchild 42, a monoplane; a Pietenar, the new Driggs "Skyline"; the Lockheed W-30 motor amphibian; and the Lockheed "Pilotair," a newly designed low-wing two-place flying boat.

Besides the two Cessna monoplanes the Cessna exhibit included a new training glider which attracted much attention. In fact, judging from the large number of persons that inspected it and the glider exhibited by DeForest Aerobics Corporation it would seem that the glider market would be a good one for exploitation by the manufacturers of powered planes. So far as the planes themselves were concerned, the public seemed to be most interested in a very large and the very small models. The monoplane and flying boat did not attract the attention that might be expected. However, that was not true of the amphibians.

Many outboard models of engines were in evidence in the St. Louis show than at any previous exposition. Among them were models of the 100-hp. Conquest, the Wright J6-5, the Conquest, the Continental and the Tiger. Of these the Conquest deserves especial mention. The manufacturer of this engine not only showed a crankshaft and piston and rod assembly that rotated as it does in an assembled engine when in operation, but a comparison of one cylinder and the crankshaft designed to drive the novel valve action and timing of the power plant. These engine builders that did not show working models exhibited various parts.

A WORLD of displays arranged by the engine manufacturers were warrently massive. Chief among them were the Pratt & Whitney, Curtiss, Continental, Wright, Fairchild, Conquest, Michigan Aero Engine, Knicker, Chevrolet, Lambert, Western Enterprise, Tiger, Warner, Lycoming and the Bass "Tupac" exhibits. Interestingly, Fairchild Engine Corporation, Warner Aircraft Corporation, and Knicker Airplane and Motor Corporation exhibited new models.

The Knicker exhibit was perhaps the most unusual of all. The back of the booth was of red plaid, with the name, "Knicker," emblazoned against it in red letters. Below the name sign were the words, "Now 100 Horsepower Motor." The floor of the exhibit was raised per-

haps 6 or 8 in. above that of the exhibition hall, and was carpeted. There were two entrances at the front near the ends. Between these entrances, and at the ends of the exhibit were wood and plaster-board partitions with underframe pillars at the ends and corners. These were done in yellow, red, and black. The entire use of the three engines on display was the new 195-hp. five-cylinder power plant, while the others were of the 100-hp type. One of these was the outboard model.

The Conquest Engine Corporation booth should be mentioned also. The design was not out of the ordinary. However, its design lay in the fact that it is portable. As a matter of fact the booth was nothing more or less than a large screen, with dark blue velvet hanging in

The well laid out exhibit of the Conquest Engine Co.

lense folds from the aisleded fronts. The shape can be changed as a result of its construction to fit in spaces of various sizes and heights. It will probably be seen at other shows in the future in which Conquest Engine Corporation is an exhibitor.

Two of the most attractive of the accessory and auxiliary manufacturers' exhibits were those of the Benetz American Corporation and Aluminex Company of Amesbury, the Benetz display included exhibit of Scripps, magnesium, Edgemoor, Sturges, Bendix, Knicker, Pioneer Instruments, and Stenograph exhibitors. The Aluminex Company showed samples of its products now widely used in aircraft.

The National Show conducted annually by the Aeronautical Chamber of Commerce is an excellent criterion of the development of the aircraft design. That being the case there is but one conclusion to draw—a temporary platform has been reached in design which opens an indefinite possibility to the construction of an airplane in automobile construction, although at least it can be assumed that the airplane is permanently established.

Airplanes AT THE Show

An Analysis of the Group With Descriptions of the Newer Types

By LESLIE E. NEVILLE

Technical Editor of AVIATION

REFINEMENT of detail rather than radical departure from conventional design standards was the keynote of the group of airplanes, engines, and accessories exhibited at the National Aeronautical Exposition held February 15th to 22nd at St. Louis, Missouri. Although the display might have been a disappointment to those looking for sensational new types, there was an element of interest in examining the details of designs which have undergone a gradual evolutionary process. By making a study of these details it is possible to gain up to some degree the progress of engineering.

Several of the visitors had hoped to see the Autogiro and the tandem engine installations that have caused so much comment during the past year. The floating aircraft embodied in the design of the Curtiss Tanager were probably the most unusual departure from standard aerodynamic practice. It was the only plane having wing tips and fins, while the Whittellay Avian had lost those.

It is our intention to devote this article to an analysis of the airplanes as a group with special attention to the newer models. The engines and accessories will be considered in detail in the March 8 issue. Comparison will be made with the exposition held in connection with the National Air Races in Cleveland last August and also with the Detroit show of nearly a year ago. A comparison of the characteristics of these three groups of airplanes is given in Table I.

The question of monoplane or biplane does not seem to have changed appreciably during the past year, and in that respect the airplanes at the St. Louis show seem to have been almost equally divided, with a suggestion of increase on the part of the monoplane and a decrease on the part of the biplane. The proportion of monoplane type seems to permit fairly accurate.

The proportion of closed and open planes also seem to be very nearly equally divided. A slight but significant drop is noticeable in the proportion of land planes at the St. Louis exposition and a corresponding increase in the number of amphibians, flying boats and amphibians. Single-engine craft still tend by a large majority while there are relatively few two- and three-engine planes as has been the case before.

While the table shows that there were six of the eight-place planes in the one-place class, this may be somewhat misleading because of the fact that these were about equally divided as to purpose, one group being for sport

and secondary training use, while the others were made carrying types having space merely for one pilot. The Cessna "Carrier Pigeon," Great Lakes, and Pietenar are examples of the latter group while the Aeromacs, Baby Ace, and Flashy, represent the former.

The straddle existing between the two- and three-place plane groups is interesting. Although there were twenty-three two-place and twenty-four three-place airplanes at St. Louis, the proportion of their total to the total number of airplanes at the show is somewhat smaller than it has been in the past. This might be interpreted as meaning that airplanes are now being built for specific rather than general purpose. Advances have been made by the four-place type, most of which are the "cheapest" closed monoplane models and several interesting aeroplanes were included in the group displayed at St. Louis. The first fact there was an excellent representation of the larger transport planes ranging in capacity from twelve to twenty-two persons is partly due to the increased space facilities at St. Louis and partly to the rapid development that has been going on for the past year in the design of airplanes of this category.

Amphibians powered with radial engines are still far in the lead, but not quite as much so as they were at Cleveland and Detroit. The vertical and inverted in-line types, as well as the water cooled, exclusive of the C-15-5 were more in evidence at St. Louis, the latter by virtue of the presence of the Curtiss "Carrier Pigeon" and Conquest planes which are the first to supply the Curtiss Conquest engine commercially.

CLASSIFYING the airplane as to horsepower range, a slight increase is noticed in the broad from 6 to 30 horsepower, while a marked decrease is observed in the 30 to 150 horsepower range. Recent engine development has given rise to a considerable increase in the 150 to 200 horsepower range while those in the 200 to 300 horsepower group have nearly doubled since last year's Detroit show. The inverted in-line low wing monoplane, which reached its height at Cleveland, seems to have diminished to a level even lower than that of last year's Detroit show. There were no airplanes at St. Louis of the so-called center wing type and a substantial drop in number of folding wing machines was observed.

Approximately thirty-five per cent of the landing gears were equipped with Oleo shock absorbers of various

The uncovered wing

notable case, that of the Peking Universal, the center section transparent portion has been raised a few inches above the level of the upper surface of the wing and extended back conformably behind the cockpit affording unusual visibility ahead and to a certain extent behind.

Clearer instrument boards and seat instrument panels are being used periodically in the so-called emergency types of cable monoplane and the number and disposition of control devices is being minimized in such a way as to present a less complicated appearance to the controls in the tandem and sporting type of plane. Rudder pedals are being used increasingly in this type and in fact in most types except the open biplane intended primarily for racing. In the airplanes intended for private pilots, the left-hand throttle is being replaced by a throttle knob placed in the center of the instrument board and intended to be used by the co-pilot or either of the front seats. A greater number of airplanes are also being equipped with dual controls, one set of which can be disengaged by the person operating the other set in the event of cases of freezing to stick or jamming of rudder controls. Attention is being paid to the important problem of heating and ventilating, as shown by the more heating plant designed for the Curtiss "Condor" by the Foster, Vorse Company, each of the two seats of which weigh but 12 lb and utilize centrally six ounces of water.

There were relatively few NACA cooling air airplanes exhibited at the show. Most airplanes then at previous exhibitions were shown with interchangeable fans or fans.

Interchangeable ski equipment was shown at the Bunting NB-3 plane exhibited in the Arena. These skis are constructed of wood and are attached to the axle by means of a truncated cone shape cone of laminated wood

Detail of ski landing gear of NB-3

bolted to the main portion of the ski and having a hole to take the axle. Shock cord is provided for the forward portion of the ski and stopping cables are attached forward and rear to arrest the travel of the ski about the axle. A wood tail ski is also provided that is easily interchangeable with the regular tail ski of the plane.

The program of metal construction is still apparent but wood remains the favored material for wing construction and fabric for covering. An interesting display of spruce cut in specification was shown by the Percy Manufacturing Co.

One of the most recent developments of the Curtiss-Wright Corporation was the Kingbird seven or eight place two engine cabin plane, which attracted considerable attention at St. Louis. The Kingbird is a high wing, externally braced monoplane powered by two Wright Whirlwind engines mounted in outboard nacelles beneath the wing. The pilot sits in the immediate nose.

Behind the pilot's compartment are seats for five passengers and a removable seat for a sixth arranged in two

rows with an aisle between. Further aft is a baggage compartment and a lavatory equipped with toilet and wash basin.

The passenger seats are reclining chairs, upholstered in leather, with high backs and box spring bottoms. These chairs are the same as those used on the Curtiss Condor.

The cabin has large windows of non-removable glass. The walls are upholstered in leather up to the window

Side compartment detail of the Kingbird having "luggage" rack

line and in cloth above. Trimmings are in walnut. A carpet covers the floor.

Ventilators and steam heating are provided. The walls are insulated against cold and noise by a special material installed between the upholstery and outer covering.

The greater part of the Kingbird's structure is built of aluminum alloy but heat treated steel is used for the more heavily stressed members. The wing beams are chord tubes in the main panels and welded steel tube beams in the outer panels. Ribs are built up of dural tubes riveted together.

The fuselage structure is of aluminum alloy tubes riveted into channels or steel fittings at the junction points. The section including the cabin is covered with fabric. A vertical fin and rudder is placed in the stern of each propeller. A rubber airtail wheel is provided, and oleo and spring shock absorbers are installed both on the landing gear and on the tail wheel.

THESE CLASS of airplanes completed just in time for the show was the Irvin Prowler (M-1), a convertible flying boat or amphibian. The design is to be produced as a flying boat with the LeBlond 60, American Cirrus or Wright J-6 engines or as an amphibian with the American Cirrus or Wright J-6 engines. The resulting five models which are similar in dimensions have a weight range of 150 lb. to 1,070 lb. empty and a gross weight range of 1,265 lb. to 1,675 lb.

The Prowler is a two-place, externally braced, open monoplane with a pusher type engine installation, the engine being mounted on struts above the cockpit. The wing span is 36 ft. 8 in. and the chord 72 in. while the length is 35 ft. and the overall height 8 ft. 4 in. Dihedral is 5 deg., incidence 4 deg. and sweepback 4 1/2 deg.

The wing has an area of 198 sq. ft. of which 29.3 sq. ft. constitute the aileron surface. The area of the fin

THE Curtiss "Condor" TRANSPORT

The rear fuselage and tailfin

Left half of the engine mount

Detail of upper elevator control

Wing ribs and internal struts

Detail of wing construction

Completed wing ready to be assembled

in 13,275 sq. ft. and of the rudder 117 sq. ft. while that of the stabilizer is 28.8 sq. ft. and the ailerons 19.5 sq. ft. Wood is used in the hull structure and Alclad is employed as sheathing. Spruce wing beams with steel ribs constitute the wing structure, with sections and plywood dive struts, while the covering is of fabric. The tail is attached to the hull by means of a single outrigger built up of welded chrome molybdenum steel tubing with fabric covering and triangular in section. Spruce beams and Alclad ribs with fabric covering are employed in the tail structure. Dimplest type of tires are optional for use with the retractable landing gear.

The Skybrk, which was introduced at the St. Louis show by the Driggs Aircraft Corporation, is a small bi-plane of clean appearance using an inverted Keweenaw engine.

The wings are of wood and duralumin construction and are fabric covered. The ailerons are of the Fessie type and are made entirely of duralumin, being used as the lower wings only. Both cockpits are protected by large circular hoods of steel for safety of the occupants.

The plane is designed for a useful load of 900 lb. and

The Skybrk shown here at the Aerocon

a total weight of 1,371 lb. It has a wing area of 185.6 sq. ft. with a wing loading of 24 lb. per sq. ft. The engine develops 77.1 hp. at 1,975 r.p.m. giving a power loading of 17.6 lb. per hp. The span of the plane is 28 ft. 3 in. and it has a 22 ft. 8 in. length.

THE SEVEN REMONTEAER airplanes at St. Louis also included the Skybrk SR-3 powered by the Aerobee monoplane developed by the Aerobee Corporation of Wichita. This machine is a one passenger externally braced type, designed solely for the accommodation of flying free towed transport license requirements. The wing has a span of 22 ft. 8 in. and a length of 17 ft. 5 in., and a gross weight of 800 lb. The wing loading is 24 lb. per sq. ft. while the power loading is 20 lb. per hp. Other available power plants include the Salsman race cylinder 60-hp. engine, the three cylinder Anson, or the La-Hoad 60.

The Aeronautical Corporation of America exhibited its Aerobee at the St. Louis show. Powered with a two cylinder 30 hp. opposed engine of 4 1/2 in. bore and 4 in. stroke, the plane was designed to carry one person but has been flown with two shod. It is extremely low in price and has been designed for rapid production.

The engine was designed and will be built in the corporation's own factory. Jack A. Rothe was the designer of both plane and engine.

Among the five airplanes exhibited by the American Eagle Aircraft Co., was the new four place monoplane with folding wings designed for the Wright J-5 or J-6-7 engines. One of the airplanes in this exhibit was powered with the new Keweenaw 140-hp. engine.

One of the late arrivals at the show was the Leont biplane which is probably most adequately described

by its advertising slogan "all metal but the tires." The Leont is a three-place tandem cockpit, single bay biplane powered with the Continental A-70 engine. The fuselage structure is constructed of riveted open section aluminum alloy members and the skin is also of aluminum alloy, corrugated material being used on the sides and flat on the top and bottom. Wing structure is built up of aluminum alloy tube spars and ribs and the covering is flat sheet. It is interesting to note that, despite the metal construction, the gross weight is less than 2,000 lb.

FAIRCHILD's EXETER centered around the new "43." This plane, seating four, is a high wing, cabin monoplane. It is powered with the Wright J-6 engine. The wings are of the well known Fairchild lifting type. The landing gear has a wide track and shim or shock absorbers are quickly adaptable. The cabin is spacious and baggage compartment and toilet room are located in the tail.

Although it has been in production for some time, the Commuter, competitor to the Keystone-Loring "Air Yacht," was among the new planes having their debut at the St. Louis show. More streamlined than the average amphibian, it retains the rugged features of the "Air Yacht," an interesting new model of which was shown.

The front work of the Commuter hull is built up of duralumin shapes bolted together. The idea is of sheet metal riveted to prevent corrosive action. The skin is bolted to the frame, no rivets whatever being used in the hull's structure.

The biplane wings are of 36 ft. span and have a 6 ft. chord. Spars are of special construction with ribs of Alclad.

Car and its shock absorber to accommodate ditches

Reinforced control stick on Curtiss biplane

Wings and all control surfaces are fabric covered. The wheels are hydraulically raised or lowered by a small hand-operated lever pump. "Aero" shock absorbers are used on both wheels and tail skid.

The plane seats four persons, the two front seats being complete dual control. In addition to the main hatch entering the cabin at the rear, a smaller hatch is provided in the front for convenience in picking up entering loads and alighting at the dock.

The Commuter is powered with the J-6 300-hp. engine. The propeller is placed in such a position that no one need

ever with it to get in or out of the cabin. Electric motor and pulleys are standard equipment.

Improvement in the new model of Tri-engine plane includes simplification of the external wing bracing and addition of internal drag bracing in the conventional manner. Slatted ailerons have been incorporated in this model necessitating a false spar for their mounting and giving the general appearance of tapered wing in the straight wing type. The new airplane embodies the use of a tail wheel to replace the dolly in the previous model and the wheel may be locked when it is desired to use the airplane for training. The wheel also can be replaced by a dolly and the mounting has 360 deg. swivel action with a spring device for cushioning. The spinnable wheels, stretched by dies to the desired shape, are used in the new models and this process has been found successful.

The wing landing gear has been slightly modified in the new model and one of the members of the top structure eliminated. The present type has a vertical shock absorber strut, the upper end of which is welded to a short horizontal member which it in turn is welded to the lower fuselage member. Another member welded to the upper fuselage is attached by welding to the joint of intersection of the vertical and the horizontal struts.

A feature of the Detroit Aircraft Corporation's exhibit was the unveiling of the new Ryan Pursuant. This plane is built along the lines of their previous models and is powered with a Wright J-6 engine.

The upholstery and seating arrangement are worthy of note. The back of the right front seat folds down joining the rear seat and forming a comfortable lounge on which the traveler may take a nap. All other seats are adjustable in several reclining positions. The upholstery and interior trim are made in match throughout. No cables or other parts of the control mechanism appear above the floor. An auxiliary stick for instruction purposes may be inserted in a few minutes. The brake pedals are conveniently located just above the left and right rudder controls.

A departure from Ryan practice is that the wing is made in two panels and a small ribbed is used. Steel cushions placed this are used throughout with dual compression members. The model on display at St. Louis

Sketch of side view of the Ford tri-engine

used the J-6 Wright Whirlwind engine. The plane may be built with any other power plant up to 300 hp.

Inter-acting elevator horns were new features of the Ryan airplane and Eastern Flying Boat is the Detroit Aircraft Corporation. These horns are actuated by internal push rods and when the elevator is in down position, the upper end of the horns moves into a recess in the lower portion of the vertical fin. This simplified arrangement eliminates drag producing and unsightly struts or cables and horns in the air stream.

Although not a new type, the Lockheed Stron was displayed for the first time in the exhibit of the Detroit Aircraft Corporation. The Stron has a structural resemblance to its predecessor the Lockheed Vega, but differs in that it is a low wing open monoplane, the two passengers in tandem seating arrangement. The advantage of the monocoque construction is taken to provide an unusually high degree of streamlining while wheel fairings and a NACA cowling also contribute

Sketch of the Lockheed Stron

to the aerodynamic efficiency. It has a wing span of 42 ft and a length of 27 ft. The gross weight is 6,200 lb and the total wing area is 385 sq ft.

Those who placed the Fleet exhibit are to be commended on their method of presentation. An uncovered wing structure showing the ingenious aileron control a landing gear unit showing the use of the air wheel, and a tail unit showing the simple stabilizer adjusting mechanism, were indicated in addition to the standard Krone power tractor shown.

Two new Stinson models had their premiere at the St. Louis show. The first of these, the Stinson Speedster, follows closely upon the C-38 model which the industry has become familiar. With the introduction of the new series of Wright engines Stinson engineers decided not only to replace the engine in the C-38 model, but also to reverse the design of the plane. The Stinson Speedster is the result. All the appointments of the plane have been very much improved. The display model of the Stinson Speedster which was shown at St. Louis had a fuselage painted in silver gray and the wings done in international orange, both colors being prescribed by the American Visual Congress.

The second member of the Stinson family, also shown for the first time at St. Louis, is the Junior Speedster. In general lines and appearance this plane follows the standard Stinson practice. The plane is equipped with NACA cowling which was developed by Stinson engineers with input into both maintenance and aerodynamic problems. The landing gear is of the shock absorber design but employing a hydraulic spring unit instead of the rubber disk type found on the C-38. The tail wheel rotates through 360 deg.

In the pilot's cockpit controls are readily accessible and an inferiorly lighted instrument panel is conveniently placed before him. The pilot's seat is adjustable.

ing a pay load of approximately 750 lb to be carried. A removable metal plate on the underside of the fuselage provides ready accessibility to all controls and inspection. The Speed Mail on display had for a color scheme Berry Blue, yellow, blue and black with silver striping.

The Business Speedster has an overall span of 25 ft. as compared to the 38 ft. span of the Junior Speed Mail. The wing area of the Business Speedster is 288 sq ft. while that of the Speed Mail is 347 sq ft. The Junior Speed Mail will be produced in two models. The CAA will be powered with a Wright Whetstone while the COW will be powered with a Pratt & Whitney Wasp. The gross weight of the Business Speedster is 2,700 lb., that of the Junior Speed Mail being 1,800 lb. and 1,900 lb., respectively, for the two different engines.

Four new models, all of the enclosed cabin type were announced by Stinson as their 1938 offerings.

Three models of the Stinson-Detroiter Junior four-place cabin plane were shown, the bottom model being equipped with a 220-hp. Lycoming engine. This engine, known as the 30-60, is now in production, after having been under development for more than two years by the Lycoming Manufacturing Company of Williamsport, Pennsylvania. One of these models was equipped with a 325-hp. Wright engine and the third with a 300-hp. Wright. In construction, the plane is a duplication of the 1937 Stinson Junior.

Two models of the Stinson-Detroiter Senior type were shown. One was a six-place cabin plane, equipped with a 300-hp. Wright engine and the other an eight-place cabin type with a 425-hp. Pratt & Whitney Wasp.

The latest model Versatile air coach was exhibited and was an unusual combination for its beautiful finish. See-

Optional air equipment of the B-42 amphibian

ing additional items have been made to its equipment since the last drawing. These include retractable landing lights in the lower surface of the wing, an optional electric air starter, and a tank situated in the rear of the cabin.

THE LARGEST plane of the Curtiss-Wright exhibit was the Curtiss Conquestor and it attracted attention proportionate to its size. The plane is powered with two Curtiss Conquestor B-150 water-cooled engines of 635 hp. each. The engines are geared at the rate of 2:1, giving a propeller speed of 1,300 r.p.m. The plane is of the

biplane type. The interior of the cabin is divided into three compartments, each compartment accommodating six passengers and it desired it may be completely shut off from the other two by means of doors. The interior finish resembles wood paneling and is very attractive. Exceptional provision has been taken in the construction of this plane to dampen the noise of the engine. Accessories which may be included at the option of the operating company are four sleeping berths, full bathroom equipment for night flying, a desk set, heater, and a refrigerating system. A greatly improved seating arrangement was embodied in the Conquestor shown at St. Louis.

Passes enter their forward compartment through a door in the floor and without passing through the pas-

Sketch showing the tail end of the new 1938-9

senger cabin. The ladder for this entrance folds back over the plane when not in use. Full two-way radio communication is provided on the plane.

In the Curtiss-Wright exhibit was also included the Carrier Pigeon II. This plane was designed to carry large loads at high speed with little, if any, increase in the use of the power plant. The plane uses a geared Curtiss Conquestor engine. The firm of the plane are very fine and it is very well streamlined.

The Conquestor engine, a twelve-cylinder power plant, develops more than 600 hp. It is connected by a two-coarse reduction gearing to a Curtiss-Hord radial propeller having three adjustable blades. The engine and radiator are completely cowled in, and the lines of the cooling bleed perfectly into the fuselage.

To facilitate the emergency efficiency of the plane the landing lights have been made retractable. The navigation lights are built into the wing tips, and the tail wheel and its strut are enclosed in a steel metal fairing.

The Carrier Pigeon II is a single bay, winged plane, staggered biplane. The top wing is considerably forward of the lower wing and is slightly larger. The fuselage is of the semi-monocoque type in the front compartment section, with the skin of the fuselage built to carry a part of the load. The rear compartment, which has a capacity of 145 cu ft., is free of housing and is made entirely of metal. To facilitate the replacement of parts of the fuselage, it is constructed in three sections, built separately and bolted together.

The pilot can make three adjustments of his seat in flight, moving forward or away from the rudder pedals as he desires; raising or lowering the seat 10 in. and adjusting the angle of inclination of the seat back. By means of a hand lever, the rudder pedals may be made to operate both the rudder and wheel brakes or the rudder only.

promotion plan developed by the League Aeronautique Corporation and presented by L. C. Perkins of that organization. Starting from the premises that the industry is over-organized, with too much capital per airplane and too few planes per airport, and that the general public has not yet generally accepted flying, Mr. Perkins argued for the creation and found them in four and in mistakes beliefs that flying is very costly, that it takes a long time to learn the art, and that only a man of extraordinary qualities can hope to practice it successfully. Indirect causes have been the failure of airplane dealers to follow evidence-once-upon-a-time and the unfortunate freedom of money of them for sensational exhibitions which gave aviation the worst possible publicity. The future, he believed, would depend upon business men outside of the industry more than on the technical personnel inside. They can be attracted by giving the money out of flying and by rethinking through leaders in their community, men to whom they would have confidence. Mr. Perkins was sure that a plane could be sold to at least one out of every five hundred automobile owners. That alone would insure more money than sales in the United States. Taking automobile ownership as the basis, therefore, he believed very strongly in the desirability of covering the sale of airplanes with that of automobiles. The overhead of the airplane agency could be eliminated; while the airplane would benefit the automobile dealer by giving him favorable publicity and by attracting new classes of visitors to his show-room, the salesman is the direct return from the sale of airplanes, his business in passenger cars should also profit.

PERKINS OUT that there were over 53,000 automobile dealers in the United States and that their personalities as a channel of airplane distribution had hardly as yet been touched. Mr. Perkins explained at length the education and selling campaign planned by his company for reaching that group and for showing them how they could make a profit out of selling a line of airplanes to their present clients, and how they could at the same time keep practically all their capital liquid, as pilot-salesmen-instructors would work on commission and drawing salaries.

Perkins' suggestions were received with great interest and warmly discussed. Some possible difficulties were uncovered. It was reported for example that several of the largest automobile companies have specifically notified all their dealers they are prohibited from engaging in the airplane business, either because they object to the suggestion of effort to increase sales, or because the dealers in fact, for their own possible future airplane activities. Mr. Perkins' talk led all into a general discussion in which S. L. Wilkins, of the Sperry company, Richard H. Depece of Fairchild, I. A. Nixon of Air Transportation, and the writer were leading participants. Salaries were viewed against the apparently impending danger of a price war and also against high postage advertising methods, floating planes on purchasers who have no real use for them and from whose hands they would specially fly back into the mid-plane market. The manufacturer, said Mr. Taylor, must cause his interest in the purchaser and in the service that the purchaser gets from the plane, and must catch him on how to get the most out of it. Another suggestion very favorably received, although not actually voted upon, was that there be formed a protective vigilance committee to watch upon the price, not to suppress

factors but to insure against under speculation or interference with an aggressive positive organization. Although this scheme was well received as a whole, there were other participants in the discussion who were prompt to urge that the overall industry's troubles begin at home and that a vigilance committee should start its life inward as well as upon the daily price.

S. L. WILKINS

a physical examination and secured a student's permit. Mr. Perkins also presented his plan to the engine manufacturers, from whom it evolved on the whole a more warmly sympathetic response than from the airplane group, notwithstanding the fact that particular application of his scheme was focused on pushing the sales of C.O.S. ships. The representatives of the engine builders displayed great confidence that private ownership could be much extended by proper selling methods, and examples were cited of dealers and mail manufacturers who had been especially successful in developing that market not only because of their great personal skill as sellers but also because, following the line of Mr. Perkins' thought, they possessed the genuine confidence of their communities as sold and self businessmen.

Membership of airplanes abroad was apparently of less lively interest than that at home, for the report of the export committee was accepted with but little discussion. A standard foreign distributor agreement has been prepared as the result of some months' experience with a tentative form and a detailed outline concerning some forty thousand titles, is nearing completion.

An extensive hand-book on aeronautical export practice, containing detailed accounts of the economic values, the aeronautical equipment, and the growing flying conditions and aircraft markets in all the countries of the world is underway, with the cooperation of the Aeronautics Trade Division of the Department of Commerce.

THE ENGINE MANUFACTURERS' section, like the others which had their meetings in St. Louis, had a chairman and an executive committee to elect. Like the airplane manufacturers, they elected their present chairman, Frank H. Russell of the Curtiss Company. The other members chosen for the executive committee were W. H. Reed of Lycoming, R. H. Bailey of Continental, C. W. Woods of Pratt and Whitney, Fred A. Worthing of Anzalone, D. L. Brown of Pratt and Whitney and C. L. Lawrence of Curtiss Wright.

The engine manufacturers' discussions naturally largely paralleled those of the airplane builders. The meeting

was strongly favorable to a continuance of the newly established policy of collecting monthly reports and making them include both production and sales data. There were, however, a few points that production figures would be inadequate, and that only sales were satisfactory. One or two speakers with previous contacts with the automobile industry, noted, as it was to urge that the present role of working all reports in the offices of the Chamber of Commerce, and distributing only total figures, should be abandoned in favor of the practice of the National Automobile Chamber of Commerce, which receives sworn statements of sales from each of its members each month and distributes to them a table of sales made by each company with the understanding that the information so furnished will be held absolutely confidential.

The personal topic of discounts and engine service played, as usual, a leading part in the discussion, and followed him who had been almost alone throughout. Again there was raised the question of who will be responsible for the servicing of engines, of whether the airplane manufacturers can, through his local distributors, undertake that task or whether the engine manufacturer must discharge his own service station. Again there was debate on the relative discounts which should be allowed on spare parts to engine distributors, to local dealers or sub-dealers carrying only a very small stock, to airplane manufacturers, and to operators, during the time of servicing and buying parts in large quantity.

The prevailing sentiment of the engine manufacturers seemed to be that at the present time there was not, with rare exceptions, enough business for any sort of report in any one type of airplane in any one locality to justify the airplane dealer in preparing to give proper engine service. While the engine builders have no inherent longing to be bothered with the maintenance of service, they feel that they must undertake it under present conditions, if a properly efficient and national service organization is to exist.

There is no general agreement among the airplane manufacturers as to the method of service of engines. That of course, absorbs the vast majority, perhaps nearly to ninety-five per cent, of the total engine output. The representatives of one engine manufacturer proposed that, in accordance with the usual practice in supplying proprietary engines in the automobile industry, there should be no question of discount at all because there should be no list price on the engines. The only figure involved would be the net price of the sale of the engine to the airplane manufacturer, and that would be separately negotiated in each case, depending upon the quantity sales, the time at which deliveries were made, the skill and intelligence of the airplane builder to give a few order extending well into the future, and so forth. That, however, would have unduly increased the price at which complete engines would be sold, either by the engine manufacturer or by the

MR. HALCYON DAVENPORT, who presided at the Chamber Air Industry Session.

airplane company acting as his agent, to the ultimate consumer who wants a spare or a replacement for his plane.

Like the airplane manufacturers, the engine section found little ground for serious complaint in their present relations with the Department of Commerce. The engine speed regulations, upon which some heat had been developed in the Cleveland meeting, went by without remark. Only one definite resolution was passed, to reserve requests already made that the Aeronautics Branch should withdraw the making of dynamometer tests for approved type certificates in the manufacturer's own plant rather than at the Bureau of Standards, with the proviso that the testing equipment shall be satisfactory to the Department's technical personnel.

THE FIRST ASSEMBLY of the representatives of the aircraft industry with Secretary Young and other officials of the Department of Commerce violated a precedent. For the first time as several such meetings, the existing regulations were not the principal topic of discussion. They were not, in fact, mentioned at all except in connection with gliders, and it was the general belief that the glider movement, which had succeeded them in the first rank as a basis of controversy.

Clyde V. Cowan, one of the several airplane manufacturers who have taken up the commercial building of gliders, precipitated the debate by expressing the hope that Secretary Young would find, and fully justify himself in recommending the use of gliders in the development of gliders. He thought it dangerous. He thought it had publicity for the glider movement, a movement which could be of the greatest service to aviation if properly handled. He was unanimously opposed to airplane towing, at all times and under all circumstances. Mr. Cowan's opposition demanded special weight, as members of the gathering with experience in gliding realized, because he comes from a very flat section of the country, where it is difficult to make shock-and-drag glides of any considerable duration and where the temptation to range in all forms of gliding is very strong.

For Mr. Cowan's plan there was almost unanimous support. Airplane towing had no one to say a word in its behalf, except for one suggestion that it might be well to permit its experimental continuance under proper regulation in view of its possible commercial utility in some indefinite future date as a means of disposing birds in flight.

From airplane-towed flight the meeting drifted onto glider regulation in general. Although they were not very sharply and explicitly voiced, it was evident that two schools of thought existed. One group would keep glider construction under the same airplane regulations, in fact, and lift no sympathy for the individual enthusiast referred to as a "backyard builder." The other recognized the stimulation of engineering initiative as one of the glider's merits, and would encourage amateur design and construction so far as could be made consistent with safety. As one speaker put it, "the most essential thing is to find out whether or not the glider builder really knows what airplane construction is like and what precautions should be taken. If he knows that, the chance of his building a ship inside an ordinary glider frame, providing he works from approved blue-prints or from a properly organized design office, is very small. Whether or not he knows can ordinarily be determined in a five-minute inspection of the completed airplane." Several other participants in the discussion voiced like

dred issues for a very instant type of inspection and control, but there was mutual agreement on the desirability of some sort of supervision. Mr. Harrison, of the Conquest Engine Co., believed that national control and the universal issue not to get lost would provide sufficient safeguards but his opinion found few echoes. It was suggested by several speakers, and seemed to be accepted by a reasonable first step that the Department of Commerce should prepare an advisory code of acceptable rules and practices in glider design, construction, and operation, and that it should be distributed as widely as possible with the moral support of the Chamber of Commerce and presumably through the National Glider Association in the active areas of distribution. Lee H. Palmer, of the National Safety Council, assured the meeting that the cooperation of the Boy Scouts of America could be counted on.

In discussing the Department's problems in the glider field, Secretary Young had emphasized the need of some standardized method of dealing with the real or design. Critics of approval might be misled by the drawings, but when blue-prints had been added to a hundred questions all over the country it was impossible to be sure either that they would follow the needs represented or that they would be understood. It was agreed to be up to the required standard. He explained, however, no active dissent from the view that a casual inspection of the finished product would be a great deal more difficult and efficient.

Government is to be left to the control of the structure pilot of power plants. Charles L. Lawrence, of Cessna-Wright, very straightforwardly declared himself opposed to physical examinations for private pilots. His words were received with prolonged applause, and introduced a debate which was somewhat different in regulation, and the necessity of having a physical examination and a permit before leaving the controls of a plane, even as a prospective customer taking a demonstration or as the plane's owner riding beside the professional pilot, played a large part.

The emphasis of the discussion was somewhat reduced by the fact that several of the speakers were publicly unfamiliar with existing conditions. One or two, for example, believed that the examination for a student permit was now the same as for a transport license. Even adding those circumstances aside, however, a very pronounced sentiment in favor of releasing the licensees that returned the private pilot or student was manifested. In response to direct questions from Secretary Young, one or two advocates of relaxation here and there with Mr. Lawrence's proposal in its extreme form. They would abolish all physical requirements in these classes—overemphasizing the fact that most of the thickly-populated states now demand some evidence of physical qualifications for every applicant for an automobile driver's license. Others less extreme would eliminate only the applicants unable to distinguish bright and from bright green as with other physical defects so marked as to make them really abnormal.

The test of sentiment came on two motions by Mr. Woodward, of Bellanca. The first, declaring in favor of a marked thickening of student permit requirements, was carried by approximately five to one—and a substantial part of the opposition was furnished by former members of the Aeronautics Branch opposition, now in the industry, all of whom were observed to vote in the negative. On a motion that the student

permit should be abolished entirely, the negative was upheld by almost as large a majority as the affirmative had secured in the earlier proposal. Of course, these votes had no official standing, as many companies were unrepresented, while others had two or three people as hand and all voting, but they revealed the weight of personal opinion.

Upon no other topic was there prolonged argument, but Mr. Babcock's explanation of the plan for apprentice repair stations called forth many questions and some statements of opposing policy. It was made plain that the emphasis in training was on approved manuals that came from the airplane manufacturer through the supply of drawings from which to work in making repairs. Contrary to the impression that had been given by many (including the editor of AVIATION) from the first announcement approved comes with a no compromise from subjective of the individual repair job being coloring. It reveals elsewhere the necessity for new approval of the drawings from which the repair is made and for a new stress analysis. The representative of one of the largest men's businesses declared the policy of his company against any modification of drawings. They preferred to have repair work at service centers and to have a limitation of new parts or sub-assemblies received from the factory. They thought that much safer, and in the long run cheaper, than trying to rebuild in the field. Others concurred in part, but only in part.

In the general effort to creation of the detail of the present rules, and to the offering for comment by the industry of changes proposed by the Aeronautics Branch, most of the points touched upon were of secondary significance. Mr. Rawdon, of Travel Air, thought that the stipulations for analysis in vertical drive should be made more specific, and should be accompanied by a manual of present used as the aerial engineer. Mr. Wright, of Cessna, thought that the use of a properly installed bungee cord on the stick to improve longitudinal stability with free controls should be fully authorized, even in the large planes. Several speakers thought that the present rules governing engine tests were too hard on the four-cylinder engine, and that there was no logical reason for singling that type out for a special and severe provision. The chief engineer of Travel Air, again, believed the present application of loads in wing over to be incorrect, and that the basic load should be the upper diagrams in the engine supporting structure, whereas in practice it was the lower ones that almost failed if any. There was some protest against the present restrictions on landing speed, and especially against the rule allowing the multi-engine plane a higher landing speed than the single-engine ones. All of which the Department of Commerce officials listened to carefully, and made no comment.

The Department's own objections were few and simple. The only one, in fact, that really disturbed the industry was a proposal that all airplanes should be covered with mesh for inspection and anchoring with the engine running and without hazard to the crew. This brought forth vigorous protest from the airplane plane. In the first place, they said, nobody with good sense wanted to make permanent attachment of a tractor system to its moving while the engine was still running, and in the second place, it was an endorsement of the proposed regulation as now drafted would put all tractor airplanes regardless of the present types definitely out of business.

Engines BEFORE THE S.A.E.

Society of Automotive Engineers Devotes Opening Sessions at St. Louis to Power Plant Problems

By EDWARD P. WARNER

Editor of AVIATION

THE Society of Automotive Engineers put the opening sessions of its national aeronautical meeting at St. Louis in the hands of the engine specialists. They devoted their attention between two sessions on Tuesday, receiving two papers on engine design and operation in the morning and two on test problems in the evening.

The first and the longest contribution to the engine session was made by Richard Chilton, formerly chief engine designer of the Aeronautics Plant & Engine Company, now consulting engineer for Wright Aeronautical Corporation. Taking as his subject "Airplane Engine Development and Operating Reliability," Mr. Chilton paved the way for his subsequent arrival of the engine designer's troubles by an outspoken challenge to the one responsible for the airplane structure to do their part as a co-operation to a harmonious interplay of airplane and power plant.

Reliability, said the speaker, is near to the heart and the soul of engine design, and he dwelt upon the difficulty of applying satisfactory standards and measures of reliability without a record of experience much more extended than is as yet available upon aircraft power plants. He observed, for instance, that if the manufacturers of engines hopes to establish a record of less than one mechanical failure for every hundred thousand hours of flight, his engine should have run at least that total length of time under his observation before he can estimate his own success. Few airplane engines, he said, Chilton reminded his audience, have attained even that minimum amount of operating experience, while "every popular automobile model has exceeded it many hundreds of times." The great proving ground in operation is the field and a few dynamometer tests in the factory cannot replace it. The more rapidly operating experience accumulates, the more confidence may be the hoped-for improvement in reliability and other desirable characteristics.

What is the actual status of engine reliability as a controlling factor in the expansion of the use of aircraft? The author of the paper proceeded to analyze that question upon the basis of a "consensus that safety is the factor in which air travel is regularly regarded as doubtful, and that until the leading characteristics of airplanes are drastically changed, engine failures on transport machines are inseparable with public con-

science." Recognizing the importance of a more intelligent interpretation by the public press and by public opinion of aircraft accidents and accident reports, Mr. Chilton noted the less met facts as he heard them, and firmly concluded that "no compromise with safety will be tolerated."

Toward the precaution, occasionally overemphasized, that the installation of multiple engine layouts the importance of engine reliability Mr. Chilton displayed marked coolness, pointing out the increased hazard of a forced landing during the state of normal flight in such planes, but insisting with it a note of the extreme unsatisfactoriness of such failure of a single engine during a take off or while turning sharply at low altitude.

With the importance of power plant reliability in the success of air transport and other aerial undertakings analyzed and conceded, the author went on to appraise responsibilities for giving the power plant a fighting chance to show itself reliable. He expounded accurately the model of the airplane designer, and explicitly declared that "these remarks are intended to spur the plane experts to move forward with some criticism of existing power plants as to their shortcomings in the efficiency of the completed ship. We apply engine installation drawings, showing what the plane designer is up against when he sets out to build his pushover into his and which indicate in a general way where we stop and where he begins . . . We would like a few simple airplane diagrams, showing, for example, the relation, size, and shape of the body which is going behind our engine, and what constraints guard structure for the cooling between them, and how much of this should be our business. We would like to know if the plane constructor is going to tack the tail of the tank against the bulkhead and arrange all the vent holes in the cowling ahead of the tank. Will he design the engine mount to be a complete structure in itself and so truly fit, the engine, as most the engine when bolted into place rigidly and true up a wicked assemblage of tubes?" Pursuing farther his search for a line of demarcation is responsibility and for information from the ultimate consumer, Mr. Chilton asked, "With our airplane operators coming forward and express their views upon the following? What cooler, if any, of forced bleedings per thousand hours of operation would satisfy your present safety

measures are exceedingly complex and difficult to analyze, the Aeronautics Branch has no objection, but it insists in this event that the test of the completed structure be coupled with tests of the material moving into it. It refuses to approve of a design upon the basis of static test without assuring itself that the materials used in the tested airplane at least approximate in quality to the materials possible under the specifications which will apply to the regular production.

The general condition of structural affairs Mr. Lane found very satisfactory. With aerodynamic development it was not so well pleased, and he urged more aeronautics work along that line on the nation's designers. His complaint did not, of course, apply especially or solely to American aircraft as seen by the Department of Commerce but to the whole state of the art.

THE AIRCRAFT EXPERIMENTERS of the much-discussed loading spinning regulations has largely cleared up the problem of the structural span in approved types, and removed the hazards of spins deliberately entered into at comfortable altitudes. Mr. Lane firmly believed, expressing himself in the phrase chosen as a title for the report, in the necessity of releasing with the structural span in all planes. With respect to unaccelerated spins, falls into unexpectedly from a turn at a low altitude, conditions are not so good. The speaker was very anxious to see better provision against that thing than some otherwise satisfactory planes now provide, and better control and stability generally in stalled attitudes, and he encouraged his audience to believe that substantial improvements should be in prospect.

A minor defect in lateral control, encountered in a number of cases, is the provision of inadequate mechanical advantage on the ailerons. The distance that the pilot can move being positively limited by the width of the fuselage, to secure the necessary angular throw of the ailerons it has often been necessary to use gear ratios requiring uncomfortable if not impossible exertions from the pilot. The element remedy in such instances is the use of a wheel control.

Other points of weakness, however, Mr. Lane found quite as serious as any that could be studied in the laboratory or suggested by any delicate branch of aeromechanical theory. Some designers appeared to consider that their task was done when they had laid out the structure and turned the arrangement of the cabin over to an interior decorator, with authority to let his imagination run riot. There were planes which did not go far enough beyond the maximum laid down by the department's rules in providing against fire hazards.

There were planes which were needlessly and offensively noisy, especially with high-pitched noises which Mr. Lane considered directly responsible for much accidents. There were planes in which comfort had been secured at the expense of unreasonable additions of weight, and others in which comfort had not been secured at all. Such matters demanded careful and continuous thought.

ONE of the defects of modern aircraft is the frequent failure of performance as seen by the stop-watch and benchmark to synchronize with performance as seen through the eyes of the pilot. It is a serious matter of advising against. Again the speaker indicated his regret that the airplanes were not sufficiently flexible to permit the advertisements and been what was expected of them. Failing that, he hoped for the development of independent agencies to do performance testing and certify the results. He considered the problem of some means of guaranteeing the reliability of performance as of great importance, but he made no mention of the possibility of the Aeronautics Branch taking on the work itself as an incident of approved type testing (as frequently argued editorially in *Aviation*).

As a prelude to the principal paper, the Wright Model awarded annually for the best paper on airplane design or construction, including aerodynamic and structural theory, presented before the Society of Automotive Engineers during the year, was conferred on Ralph H. Upson. Mr. Upson received the award, made in an address of presentation by Dr. George W. Lewis of the National Advisory Committee for Aeronautics as the senior member of the committee of judges, for his paper on "Wings—A Coordinated System of Basic Design," given at the national aeronautics meeting of the SAE at Cleveland at the time of the air races. (And it was awarded and discussed at considerable length in *Aviation* for Sept. 7th.) The winning paper had included a detailed analysis of the variation of structural weight and total drag with wing characteristics as aspect thickness, aspect ratio, taper in plan form, and amount of external structural bracing.

In introducing the speaker, Charles L. Lawrence, the treasurer, made brief observations upon the glider movement from a somewhat divided state of mind. Publicly confirming the great interest in glider development which his active support of the National Glider Association had already displayed, he was sure the less said showed more the possibility of an epidemic of accidents. He earnestly hoped that the Department of Commerce would take the matter in hand and enforce safeguards at least upon the structure of the machine in operation.

Mechanical Aids TO THE DIRECTIONAL SENSE

*Radio and Instruments Receive Attention from
the Engineers at St. Louis*

By EDWARD P. WARNER
Editor of *Aviation*

ON Wednesday morning, with Charles H. Colver, President of the Pioneer Instrument Co., presiding, the members and guests of the Society of Automotive Engineers addressed themselves to problems of navigation by instruments contained entirely within the surplus. On Thursday morning, with Colonel Halney Dunsen of the United Aviators Corporation in the chair, the very deeply considered subject of aircraft radio was discussed. Of the total of twelve papers given at the aeronautical meeting, five were concerned with aids to navigation and with communication.

The instrument session was featured by the first public appearance of (ex-) Lieut. James H. Doolittle as a speaker. Taking his subject from his recent work under the sponsorship of the Daniel Guggenheim Fund rather than from his own connection with the previous industry, Lieut. Doolittle talked of fog flying and its possibility from an eminently practical point of view.

His case to grips with his subject forthwith, and before abstracting his detailed discussion of the problems that had been encountered at the Guggenheim Fund's work and the way in which substantial part of them at least had been overcome under test conditions. It is appropriate to reproduce briefly his introduction and his conclusion, which together offered both a summary of accomplishment and an inspiration to further endeavor.

"The time has come when an airplane is thoroughly equipped that cannot be flown by natural means alone. That is, it must be possible for the pilot not only to retain complete control of the airplane, but to direct it to any desired point regardless of weather conditions. Furthermore, no pilot has completed his training until he has learned to fly an airplane by instruments alone without the need of any reference point outside the airplane."

"With the instruments now developed and readily available, it is possible to fly indefinitely without being able to see outside the cockpit. It is possible to leave any given point and arrive at any desired destination. It has been proven possible to land at the desired point after arriving, provided the terminal field is prepared for instrument landing."

"Although the results of these tests covered a period

of several months, during which hundreds of blind landings were made, without any mishaps, and showed conclusively that it is possible to land by instruments alone, the procedure is still in a highly experimental stage and a new means for some instrument agency to continue the tests and develop this or some improved process to a point where it is commercially applicable."

"When this is brought about, the airplane will become the safest known means of transport, as it will be the only one that can operate unimpeded by fog."

By the end of the instrument equipment used in the Guggenheim Fund demonstration is owned by Lieut. Doolittle will be only briefly mentioned, as it has recently been given in the report issued by the Fund and in the paper presented by Professor W. G. Brown at the National Safety Council meeting last October. The aerial instrument used were an artificial horizon (gyroscopic) directional gyro, and a Kollsman altimeter which could be read to ten-foot intervals.

COMMENTING on the use of the instruments, the speaker explained that the altimeter had to be re-adjusted at brief intervals to allow for changes of dynamic pressure at sea level, information on that part being received from the ground by radio, and that the directional gyroscope could be relied upon to indicate true direction only over a relatively brief period. In a long flight it would require occasional check against the magnetic compass, to determine the amount of its wandering from its original orientation. In spite of the impossibility of using it as the sole dependence throughout a flight, Lieut. Doolittle spoke very highly of the gyro as a steering instrument, since accelerations of the airplane due to rough air or change of course leave it quite unaffected and it gives steady readings while the magnetic compass will be swinging about.

The usefulness of a standard aircraft radio receiver with vibrating reed frequency meter in Lieut. Doolittle's plane had made it possible to receive voice communication and other auditory or visual indications from the radio house. In the experiments at Muroc Field the auditory type of house was used for general long-range indications, and visual indication was supplied by the

short-range beam designed to bring the pilot directly to the center of the field.

As previously indicated the description of the instrumental equipment in just summarized contained no novelty. Least Doolittle's paper, however, offered the first account in his own words of his actual piloting technique during the blind flying demonstration.

The description can best be given by direct quotation at length. "The lead-in beam was followed for about four miles. During this time the plane was gradually climbed to about a thousand feet. A 180-degree turn was made at this point and the beam followed the turn (followed the beam) to the beacon. As the beam was approached the beam became narrower and while it was more difficult to follow, the course became much more certain. The visual type of aid consisting of two vibrating needles indicated to the pilot his position with respect to the beam center. When to the right of the beam the right needle vibrated with a greater amplitude. When to the left of the beam the white screen caused by the vibration of the left needle became larger than that of the right. When exactly over the center of the beam both the needles vibrated with equal amplitude. Upon approaching the beacon house the intensity of the signal increased rapidly and it was necessary to cut down the volume control. At the exact moment of passing over the beacon house, the needles stopped vibrating momentarily and then started to vibrate again in the opposite sense. The beam was followed about four miles from the field again, but this time in the opposite direction. Another 180 degree turn was made and the field again approached along the beam path. Airplane was gradually but not at 400 feet altitude to clear of ground obstructions, in the vicinity of the field, the plane was again leveled out and a course toward the beacon house followed. This time extreme care was exercised to follow the exact center of the beam and avoid the natural tendency to fly a course nearer than a straight line. The course was held by means of the directional gyroscopes and the necessary slight changes in course made from time to time. In this case knowing the exact direction of the beam facilitated the work so it was immediately known when a wrong direction was being flown, even though the feel indicator showed that the pilot was on his course. When the directional gyroscopes and the vibrating needle indicator both showed that the pilot was on his course and proceeding in the right direction, it was then merely necessary to hold this course with very slight variations in order to arrive at exactly the desired point. In previous turns where the directional gyroscopes was not employed, it had been found extremely difficult to follow the beam into the field as the tendency when the beam narrowed down was to fly out of the beam constantly on one side or the other and difficulty was always experienced in getting back on the beam without completely recrossing it. Upon passing over the beacon house again the lead stopped vibrating and at this point the motor was throttled so air speed of 80 miles an hour assumed and the plane held with the wings absolutely level. Previous

H. H. Hooton, Jr.

experience had shown that if the rate-of-climb indicator did not indicate a rate of descent in excess of 600 feet a minute, the plane could be flown directly into the ground and the landing gear would absorb the shock of landing without difficulty. When the rate of descent was about 600 feet a minute or the landing speed above 60 m.p.h. the shock of impact was considerable and the plane landed considerably. With a properly designed long travel also, it would be possible to fly an airplane into the ground at rates of descent considerably in excess of 600 feet per minute. [The Curtiss Tanager is an example—Ed.] At 30 feet altitude the throttle was opened slightly to a previously determined mark on the throttle segment, and the rpm came up to about 1090. The air speed was still held at 80 miles an hour, and the slight amount of throttle flattened the glide out until upon reaching the rate-of-climb indicator was showing about 400 feet a minute instead of about 1000, which was the rate of descent during the glide with power off.

Following his address, Least Doolittle qualified the statement that "hundreds of blind landings were made without any breakage" by explaining that the landing gear was slightly damaged on two occasions. He added, however, that this was negligible, for in both instances the damage was so slight as to be discovered only after the plane had been taxed in.

Departing from his printed paper Least Doolittle spent some minutes in stressing the importance of instrument board layout.

The old method of putting instruments onto a board from a water bucket has passed," he said. "With no more devices needed, instruments must now be carefully laid out in such a way that the pointers form a straight line when the crew is in normal flying attitude. Any depression is thus quickly noticeable."

It was asserted that blind landings could best be effected by flying directly into the ground with good shock absorbers rather than by attempting to sense the ground level with the instruments—a method which several times resulted in "landings" five and ten feet above the field. Attempts were made to inform the flier of his landing position by radio telephone, but this was soon

Typical altimeter charts, and the effect of temperature

discarded because the various wind, vocal, and radio reactions involved through the observer were too slow as compared with the speed of the plane. Obviously, to the observer could not see the plane in a fog of his senses.

When asked, during the discussion, concerning the sequence required for such blind flying, Doolittle emphatically replied that the average competent pilot was sufficiently capable. "I have successfully taught both a Major and a Second Lieutenant to land blind," he explained, that the Major represented the more advanced and experienced flier, whereas the Second Lieutenant stood for the younger flier element. "Of course," Doolittle added, "a flier with but a few hours is not eligible, will needing all his faculties for flying the plane."

The subject matter of Least Doolittle's paper lay on the border line between navigation and radio, being concerned with both. Doolittle's interest in radio communication in the plane was the contribution of Mr. J. B. Peterson of the Bureau of Standards, and Least E. W. Reynolds of the Navy Department's flight test section lately test pilot in the Georgetown safety comparison.

The author's primary purpose was to emphasize the necessity for special equipment carefully constructed and for the use of very special knowledge in making and interpreting tests if the results were to have any validity. Maxwell made the pitfalls revealed for the average engineer who may suppose that a general knowledge of physical science is adequate for the supervision of precision testing. Error in altitude due to differences between true static air pressure and the pressure at the point where the barograph is installed on the wing airframe, and having to be determined by connecting the instrument to a static tube outside the fuselage, errors in barograph clock rates to frequency changes, errors in temperature readings due to the direct impact of solar radiation, and numerous other sources of trouble easily easy to overlook received attention from Maxwell, Peterson and Brown. They particularly stressed the need of a check-and-balance supervision for the barograph and the importance of frequent maintenance of instruments.

The authors had no unfavorable observation to make upon the accuracy and reliability of the best testing

More altimeter charts

types of testing barographs. For ground temperature measurement on all types of airplanes, their recommendation the electric-resistance type of thermometer. For measuring rpm, the chromogenic tachometer was once considered the only acceptable type, and is still recommended, but a special note was made of the already improvement in the centrifugal type and of its longer life. The unsatisfactory qualities of flow meters were deplored, and the paper described, as the only acceptable basis for fuel consumption measurement on an airplane with a single main tank, the unimproved circulation process of starting with full tanks, closing immediately in a short shutoff and immediately descending, then lifting up again and repeating the flight but with an hour of cruising at constant air speed and altitude interpolated between the climb and descent. The differences between the amounts of fuel required to refill the tanks after the two flights in the experiment represents the hourly consumption under the test conditions.

THE LEAST TECHNICAL of the three papers presented at the radio meeting was that of Herbert Hoover, Jr., of Western Air Express. Mr. Hoover spoke from the point of view of the practical application of the difficulties encountered in introducing radio as a reliable commercial instrument and upon the consequences affecting the choice of a wave length.

Herbert Hoover, Jr.

Commercial aeronautical radio in this country began with the broadcasting of weather information and the operation of radio beacons by the Airways Division of the Department of Commerce. That service has been confined, so previously all experimental radio communication in European

countries is still confined, to the band of frequencies between 250 and 375 kilocycles internationally assigned to aeronautical purposes.

American operators have considered it impracticable to carry on two-way communication with their planes on that same frequency band. The decision was therefore reached as to of course well known and an Mr. Hoover surprised by way of introducing his discussion of present problems to reserve the band of frequencies mentioned exclusively for broadcast service to use other wave lengths for communication. The available high frequencies ranged between 1,500 to 6,700 kilocycles, corresponding to wave lengths between 45 and 200 meters.

If they were lengths of from 45 to 80 meters are found satisfactory, but at night a longer wave is needed to avoid "skip" or irregular reception at atmospheric distances. If a single channel has to be used throughout the twenty-four hours, Mr. Hoover explained that the wave length should be between 80 and 200 meters. It is preferable, however, to change frequency at dawn and at dusk, using at all times the frequency best suited to the conditions at the moment. Waves having a much more than 80 meters are in many cases objectionable, especially by day, because they are so far in excess of the fundamental wave length of the fixed antenna mounted on the airplane.

A fixed antenna is used to eliminate the effect

and also permits of communications when flying low down, eliminating the necessity of relaying a wire in and out.

The Radio Commission has worked with the air transport operators in developing a scheme of high frequency allocation in four groups. All the transport lines assigned to a single group, which will be so selected as not to be close enough geographically to interfere with each other, will operate on the same frequency. The frequency of 3,100 kilohertz (97 meters) is to be reserved for emergency or alternate use by planes not

An electronic receiver component

operating on fixed lines, and all ground stations will guard that frequency at all times.

The choice between plane and cable operation, Mr. Hoover said "was up to the individual transport company." At the present time opinion is about equally divided, perhaps somewhat favoring the telephone because of the elimination of a specially trained radio operator. Cable operation is preferable as flying over water, as surface results may then more easily be worked.

The speaker passed lightly over the technical details of equipment as they were to be the subject of other papers at the same meeting. He found cause of the available methods of supplying power to the generator extremely satisfactory. Even more unsatisfactory was the present-day ignition shielding as supplied with the equipment purchased by the air transport operators. "Up until the present time," Mr. Hoover said, "shielding has been at a minimum. No adequate method is available to the industry outside that followed by a few of the larger transport companies for their own use. In the face of this fact the industry as a whole is soon to be required by law to have reliable radio communication between planes and the ground."

In the course of the discussion on Mr. Hoover's paper, R. E. Gross, engineer of the Radio Commission, gave his views on aeronautical radio in Europe, where he had just returned. He spoke in the highest terms of the efficiency of operation as European it is, and especially of the excellent meteorological service maintained by international co-operation. He also had great praise for the British work on direction finding. The equipment, however, he considered not quite up to American standards, especially in the high frequency region, al-

most all European work being in the intermediate frequency band extensively covered by R. Gross. Added to this has been working with high frequencies for aeronautical service for some years, but the equipment has not as yet gone into regular commercial operation.

The other two papers were more technical in their nature and addressed more in radio specifications than to aircraft operators. E. M. Ryan of the Radio Development Division of the Bell Telephone Laboratories discussed equipment for aircraft communication as developed in their organization. For handling the low frequency weather report, they had a set weighing 39 lb., including the antenna. To eliminate the trailing wire, a sensitive mist 7 ft. high had been found satisfactory as an antenna warning. The normal range of reception from the average station is from 125 to 200 miles.

When the two-way communication and high frequencies became a factor, new sets had to be developed.

The particular one which they considered would transmit on frequencies from 1,500 to 6,000 kilohertz. The total weight, including antenna, is approximately 550 lb. The largest single coil of the set, the transmitting coil, is 33 in. in diameter, 16x16x10 in. in outside dimensions. Later Mr. Hoover, the author from the Bell Laboratories discussed the problem of power supply, and found some of the existing alternatives entirely sufficient. They suggested the possible drawbacks of aircraft electrical systems and of the raising of the basic voltage on large aircraft from 12 to 32. Later Mr. Hoover, too, they urged attention to the possible desirability of a small auxiliary gasoline engine to drive the radio generator.

Both Mr. Hoover and Mr. Nelson had given more than incidental attention to shielding of the ignition and other electrical units, arguing that as probably the most serious problem in radio shielding is the spark circuit, as the problem by R. A. Robertson and Dr. E. M. Hall of the Radio Frequency Laboratories was devoted entirely to that topic.

Seeking to give his audience some conception of the difficulty of the problem, Mr. Robertson explained that partial shielding might seem very effective at certain frequencies, but proves quite useless at others. To secure really effective shielding over the range of frequencies which aircraft use demands, nothing has been found to supply the place of complete metallic coating of the electrical systems of the engine and wiring. Interference is most serious at high frequencies, and shielding has therefore been a less serious problem for European than for American operators. The device of inserting a resistance in the spark circuit, for example, which has been much acclaimed in certain European countries, has been uniformly unsatisfactory against present American demands.

Mr. Robertson pointed out that there has been much discussion of the elimination of the necessity of shielding, as of the elimination of static from radio reception by adding the interference canceler therewith out, using two inducting circuits which bring in the interference with equal strength, but the desired signals vary irregularly, and then throwing the two signals each other so that only the difference of strength is audible. Although

this device has not yet been given practical application, Mr. Robertson saw in it the germ of a possible hope.

Finding attempts to replace straggly metallic shielding, work along that has been carried on by various commercial organizations, following upon the original researches and the inspiration of Wright Field and of the Bureau of Standards with great success. The shielding now available reduces the interference as indicated by charts shown with the paper by some 99.9 per cent, and the added weight of the equipment to secure that notable suppression of disturbances is a little less than 10 per cent of the total engine weight.

The shielding of wiring and magnets is comparatively simple, if no consideration is given to maintenance. When thought is taken of the necessity of periodic inspection and occasional replacement and also of the effects of oil working in through a metallic braid covering and lying adjacent to or impregnating insulation on the cable, the problem appears less simple. It will require almost an electrolysis act, however, compared with the shielding of the spark plugs.

The special difficulty in the case of the plug is the remodeling of gutter shielding with proper cooling and absence of fraying. No completely satisfactory plug, incorporating their own shielding as design, are according to the speaker's view, as yet commercially available. Mr. Robertson showed slides and spoke in very favorable terms of the supersonic plug shield developed by the Aerojet Radio Corporation and paired with cooling towers, which not only solve the cooling problem but also make the plugs run cooler than they would with engines, and actually reduce the liability of fraying. One point the speaker stressed in connection with spark plug shielding, possibly never hit anywhere before, was the absence of standardized terminals. He knew of no two shielded plugs in present using a standard type of terminal, and urged that the manufacturers should use the agency of the Society of Automotive Engineers to come to a mutually satisfactory agreement.

The interest of the subject was apparent in the discussion, for in spite of the somewhat technical nature of the paper and the fact that it had not been prepared in advance, there were many in the audience who were anxious to ask questions or to contribute their own experiences. Aircraft operators were particularly well

A Radio receiver through for performance and work

represented. Mr. Hoover commended Mr. Robertson on the progress he has in his paper, but considered that even the best systems of shielding displayed by him were not yet up to the demands of the transport companies, taking into account case of disassembly effect on engine reliability and all other considerations. He expected, however, that there would be much further progress in the next six months.

Mr. Elias of National Air Transport observed that "Most radio applications would be on the intermediate frequency side, and that were relatively simple and light forms of shielding should be available for and used by the airplanes which would not ask to maintain two-way communication. In reply, Mr. Ryan of the Bell Laboratories doubted the feasibility of making any substantial saving in either weight or money by using a sound-rate shielding. He believed that all shielding employed should be effective for all wave lengths.

Another speaker pointed out that the engine manufacturers were treating the matter too lightly, and were considering that the air transport lines could be used as their laboratory on which to play about with experimental shielded designs, contributing their part responsibility for the lives of their passengers. A representative of Universal Air Lines took a more optimistic view, declaring that the business which they developed, and which had previously been considered upon favorably by Mr. Robertson, would serve to shield the ignition and spark plugs for the normal period between engine overhauls, without requiring attention to itself.

C. Frances Jenkins, the well known writer and television expert of Washington, took the discussion onto a fresh track by depicting the necessity for any shielding at all. Using his new device [recently described in AVIATION] of a horizontal antenna held streaming out behind the plane by a miniature wind sock, he had been able to maintain two-way telephone communication over a 300 mile distance with a set weighing 25 lb., total for receiver and transmitter, and no shielding whatever. This was possibly by keeping the antenna in the electrical shadow of the rest of the plane.

Although apparently the experiment had not been tried elsewhere just in the form that Mr. Jenkins had proposed, and he argued that the transport operators saw for themselves what a horizontal antenna would do, his remarks evoked some skeptical reactions. By Perle of the Radio Frequency Laboratories declared that Mr. Jenkins could obtain only good results with a receiver of very high sensitivity. Admitting that he had not tried to use one, Mr. Jenkins said why he should. His object had not been to hideaway himself by having himself to a great sensitivity or type of receiver, but to maintain communication over an oblique distance with light weight equipment, and that he had done. Mr. Hoover observed that the high-sensitivity receiver now used had originally been introduced because the Bureau of Standards had found that the rapid vertical antenna was required for symmetrical reception of radio because irregular and the maximum vertical dimension available with a fixed mast support on an airplane could be only about five feet. Mr. Elias closed the discussion with some unfavorable remarks about static in general, with special reference to their presence for accumulating and so interfering. The idea had been repeated on several of the National Air Transport planes with an antenna mast in position behind the cockpit to just above the top of the middle, with results which appeared to be entirely satisfactory.

GENERAL NEWS

HERMAN F. FORTALL, News Editor

Many at Aviation Education Meetings

Material for '38 Activity Is Gathered by Committees

ST. LOUIS (A-1)—The National Committee on Aeronautical Education held its first Session in conjunction with the International Aircraft Show attended about one hundred delegates from all sections of the country. The meeting was concluded by William H. Spaulding, chairman of the Educational Committee of the Aeronautical Chamber of Commerce, and one object was to gather material which was to be used by that committee in its activities during 1938.

Work in Handwritten

Each delegate was one of three committees appointed to consider specific problems in the fields of college aeronautical education, ground school training and elementary and secondary aeronautical education. Two and one-half days were devoted to addresses and the experience in these three fields, after which the respective groups presented a report of opinions and recommendations to a final general session terminating the week's activities.

At a luncheon opening the meeting, Dr. George R. Thompson, Chairman of the Washington Committee on Aeronautical Education, stated that education need not only aim to give credit with long learned traditional subjects but to take the youth of the country of which aviation is one. The specialties and methods of today are important, because the traditions of tomorrow.

Following this address, a general meeting was held at which time speakers laid the groundwork for the conference.

Here Future Lies With Youth

The theme of the session, according to Dr. John W. Wilkins, chairman of the Georgetown Trust Committee of the Department of Aeronautical Education and Director of the School of Education of New York University, depends upon the education of the youth and girls of the generation and the proper preparation of teachers for competent instruction in the subject. He pointed out the opinion that the emotional needs of most adults are met by the commonest transportation needs, but that school children properly educated and made familiar with the general and increasing scope of air transportation will grow up to look upon aviation as a natural phenomenon.

The aeronautical education of children. Dr. Wilkins said must be done on a

school as well as outside of it. The answer may be brought within the realm of actual experience by clubs, group projects, construction, moving picture talks, lectures, designing and building models etc., but the experience to be used must be coupled with formal instruction in the vocabulary of aeronautical mechanical drawing, air history, economics and the like, he asserted.

Andrew D. Williams, head of the aeronautical department of Case Technical High School, Detroit, said the chief problem of ground schools lies in a shortage of capable instructors. He said some universities are training teachers for this field but it is difficult to obtain the best ones for public schools, because the demand is so great within the industry itself. He recommended an enlarged program of teacher training.

An outline of the progress of aeronautical instruction in the high schools of California and in the University of Southern California was presented by Dr. Earl W. Hall of the latter institution, who is chairman of the California State Advisory Committee on Aeronautical Education and Educational Director of the Western Air Express.

Talks of Aeronautics Services

The original air program started in the United States in 1917 when it had been incorporated in a course was being offered in the high schools of the state, which the University of California has gone to the extent that it offers a four-year course leading to a degree in the degree of Bachelor Aeronautical Engineer.

J. S. Mayhew, Chief of the Inspection Service, Aeronautics Branch, listed the many services offered by the government.

ment for assisting in the development of adequate ground schools and flying schools and aeronautical education in general.

Chairman of the committee appointed were Aeronautical Education in Public Schools, B. D. Smith, Chief of the Aeronautics, Superintendent of Public Schools, St. Louis, Education in Colleges, Universities, Dr. John J. Connelley, head of the aeronautics department, University of Cincinnati and Aviation Ground School Education, W. Harold Taylor, head of the ground school, University of Illinois.

Models and Engines Aid

Addressing the first general session, Charles S. Gurney, James president of the Curtis Wright Flying Service, stressed the chief of today is familiar with the history of aviation as told by the famous flights and exploits and that the question is to determine how much farther the subject must enter the schools. He suggested more and better model airplanes and later the construction of full-size gliders. An elementary course in aerodynamics of a national nature should include engine, atmospheric navigation and simple aerodynamics including static formation study and instrument power. Mr. Jones said.

The first group in ground school education was addressed by William S. Barnard, director of schools, Universal Training Corp., Detroit, pointed out that the ground component represents 90 per cent of the people engaged in commercial aviation and that the importance of the ground training there is a most serious problem. Mr. Barnard said that a properly done curriculum should thoroughly cover the theoretical role of the basic subjects that pertain to aviation but should be combined with practice in so as to yield the highest degree of efficiency.

Engineers University Culture Work

Edward P. Warner, chief of Aeronautics, addressed the group on aeronautical education in the higher community. Mr. Warner was formerly professor of aeronautics at Massachusetts Institute of Technology and is also Associate Director of the Navy for Aeronautics.

The ground school committee in its deliberations brought up the subject of the University's responsibility for air plane and engine maintenance. Most of the members seemed to feel that the responsibility should be placed on the competent ones are giving license and that the Department of Commerce should have the highest standards. The committee also considered the qualifications of instructors, the equipment required for shops and laboratories and methods of instruction.

Lee Schoenhair Breaks Six Weight-Speed Marks

JACKSONVILLE (A-1)—The new records were recently obtained by Lee Schoenhair, chief pilot for the Goodrich Rubber Co., Akron, Ohio, in that town's Miss Silverman, a Lockheed Vega. The marks were earned, his time and holder at the old record.

1. Carrying an added weight of 200 lb. over a 160 km course, average speed, 135.42 m.p.h. Former record held by Bernard Lane, Bronx, with 124.62 m.p.h.

2. Carrying an added weight of 300 lb. over a 160 km course, average speed, 127.25 m.p.h. Old mark of 124.44 m.p.h. held by Capt. S. J. Bond, England.

3. Carrying 1,000 lb. added weight over a 160 km course, average speed, 110.42 m.p.h.

Mr. Schoenhair

125.97 m.p.h. Captain Bond had established a record of 160.23 m.p.h.

4. Carrying an added weight of 1,000 lb. over a 800 km course, average speed, 104.14 m.p.h. Captain Bond's mark was 124.66 m.p.h.

5. With an added weight of 300 lb. over a 1,000 km course, average speed, 130.70 m.p.h. Lane formerly held the record with 145.00 m.p.h.

6. Carrying an added weight of 1,000 lb. over a 1,000 km course, average speed, 132.70 m.p.h. The mark of Paulard and Chompey of France, was 137.58 m.p.h.

R.A.C. Expands on West Coast

LOS ANGELES (A-1)—Ted Schlegler, western sales manager of the Detroit Aircraft Corp., has announced the opening of new offices in Cleveland and St. Paul. P. L. McMillan will be in charge of the Cleveland office at 1300 Triana Tower Bldg., and W. A. Wilkins will direct the office in St. Paul, which will be at the Hager Air Supply Co. All divisions of the Detroit Aircraft Corp. will be represented by the new offices.

Aero Branch Wants \$259,000 for Deficit

WASHINGTON (A-1)—The deficiency appropriation bill which was referred to the House during the session of the Aeronautics Branch of the Department of Commerce. Many of the money will be used for field inspection service and engine-testing work, although some of it will cover salary increases to engineers and the Bureau of Standards. Provision of additional staff is also made for the purpose of carrying out the work at the field inspection service and weather reporting facilities.

In bringing before the Appropriations Committee, Mr. Clarence M. Young, Assistant Secretary of Commerce for Aeronautics, said that \$264,000 is necessary to carry out additional field inspections and \$24,000 is necessary for the testing program. A sum of \$240,000 requested by the action of the department in charge of administration.

For the purpose of providing additional test capacities, facilities \$24,000 is necessary, the committee was told by Capt. F. C. Humpstead, chief of the Bureau of Standards. The money will be used by the Bureau of Standards in carrying out various research activities and the rest will be used by the Weather Bureau, he said.

For the purpose of providing additional test capacities, facilities \$24,000 is necessary, the committee was told by Capt. F. C. Humpstead, chief of the Bureau of Standards. The money will be used by the Bureau of Standards in carrying out various research activities and the rest will be used by the Weather Bureau, he said.

Norgron to General Instrument

LOS ANGELES (A-1)—The Carl A. Norgron Co., Inc., of Denver, Colo., has been purchased outright by the General Instrument Corp., and the radio plant will be moved to Los Angeles at once, according to the announcement of Stanley E. Loebler, Pacific Coast representative for the Bradsco instrument, of which General Instrument Corp. is a subsidiary. Magnification of the use of air plane compasses, pneumatic drawings, lifting cable automatic test laboratories, industrial blow valves, air pressure valves and automatic test equipment turned out in the Denver plant, will be produced in the new Seattle building, according to the company. The completion of the new building will be ready for occupancy by April first, while the new survey bureau will be completed the same time.

HIGH POINTS in the NEWS

4. **Windward and under.** Eight days ago of International Aircraft Show at St. Louis reported to have attracted some 450,000 visitors. Over its show in preparation for plans, engines, and accessories reported, (the reader may be skeptical if he would like to have reached the neighborhood of 450,000 in view).

5. **How to teach flight.** Nearly a hundred delegates discussed this problem at the National Conference on Aeronautical Education held in St. Louis during the International Aircraft Show and sponsored by the Aeronautical Chamber of Commerce.

6. **Turkey to start work.** That 1938 air program planned for 1938 by the National Aeronautics Association Board of Governors.

7. **Sir to fly to London.** In a Lockheed Vega, Lee Schoenhair breaks new world record for speed flight with loads, he merely held by England and France.

8. **Planning approval.** General Motors Aeronautics Corp. agrees to finance the sale of Lockheed air as a transportation.

9. **More blood than red.** Release that of Aeronautics, Inc., on Feb. 21, 1938, showed total assets of \$4,500,000 and liabilities of only \$28,000 and \$26,000, respectively.

10. **Spice \$229,000.** Aeronautics Branch says that amount is the deficiency appropriation bill recently reported before the House. Aeronautics. Most activities and greater activities.

11. **Free-day party scheduled.** Aeronautics, Inc., in conjunction with the Aeronautics Association, will send delegates to the first Mid-South Aeronautics Association conference, Mar. 27-28.

12. **Neater model work.** Taking off at approximately 9:30 p.m., Feb. 26, from Trenton, N.J., New York City, flying from Trenton, N.J., to New York City, N.Y., the first time a new American pilot's record of 9 ft 3 in. and setting the Gamma record record.

Imports and Exports

13. **Bravo Airfield.** The Pennsylvania State University, Harrisburg, Pa., will build a new airport at Harrisburg, Pa., which will be the first of its kind in the United States. The new airport will be built on a 1,000-acre site and will be completed by April 1940. The new airport will be built on a 1,000-acre site and will be completed by April 1940.

14. **Ticker reject.** Committee of the American Air Transport Association reports on plans for a standard contract between airlines and passengers and a standard ticket form.

Momentous Marks Famous 1908 Flight

PARIS (France)—On Jan. 13, a remembrance (see *Aircraft* Jan. 14 for photograph) was inaugurated at the airport of Vincennes, on the outskirts of Paris, to perpetuate the remarkable feat of the first blimpster in closed-circuit over France in January, by M. Henry Pommerehne, on a Vacon biplane with 28 hp. An American doctor, nearly twenty-two years ago, M. Laurens Remyer, the Air Minister, presided at the unveiling of the monument. Numerous persons were present, including M. H. Pommerehne, G. Viotin and A. Sarrac-Denis. On the monument are engraved a globe, the flight, the figures of the responsibility, a sketch of the machine, and an inscription which may be translated as follows:

"On this field, under control of the Aero-Club de France, on Jan. 13, 1908, for the first time in history, one kilometer in closed-circuit was flown by Henry Pommerehne, on a Vacon biplane and led by the brother-in-law, Gabriel Viotin, with American engine created by Léonardus, then winner of the aviation grand prize 'Percussion-Airplane' and the first of the world's records on Division 1,000 m., duration, 1 min. 28 sec."

Air Lines Traffic Reported

PARIS (France)—The Compagnie Air Union, which operates between Paris-Lyon, Paris-Lyon-Marseille, Paris-Lyon-Marseille-Toulouse, shows the following traffic figures for 1979: Domestic flights, 1,112,000 as compared with 1,040,000 during 1978; passengers carried: 17,000 as compared with 11,889 during 1978; freight carried: 2,058,000 lb. as compared with 1,800,000 lb. during 1978. On the Paris-London route 3,078,000 lb. were carried in the outward direction and 775,000 lb. in the reverse direction.

Italian Transport Reported

ROME (Italy)—Further statistics on air transport in the country have become available. (See *Aircraft* for Jan. 28, page 182). The figures are as follows:

	1978	1979
Domestic flights	1,112,000	1,040,000
Passengers carried	17,000	11,889
Freight carried	2,058,000	1,800,000

Mexican Line Reports

MEXICO CITY (Mexico)—During 1979, planes operated by Compañía Mexicana de Transportes Aéreos carried 2,763 lb. carrying over 300,000 passengers and about 4,500 lb. of mail.

Foreign Briefs (Cont.)

Moscow (Russia)—A De Havilland 27 motor, with 620 hp. Hispano-Suiza engine, was a recent parade plane race on the Soviet Russian Long Hauls. Captained by the Russian government, Aviatour Franchais was second, a British pilot third, and a Belgian fourth. M. Dorel also broke the Irish flight record by carrying the distance in 11 min., at an average speed of 200 m.p.h.

Commercial flight in Denmark, handled entirely by Danish Aviatour Co., showed little change in volume from 1978 to 1979, according to report by U. S. Department of Commerce representative.

An astronomical museum is to be opened at Tempelhof airport, Berlin, Germany.

Paris (France)—The first time in history, one kilometer in closed-circuit was flown by Henry Pommerehne, on a Vacon biplane and led by the brother-in-law, Gabriel Viotin, with American engine created by Léonardus, then winner of the aviation grand prize 'Percussion-Airplane' and the first of the world's records on Division 1,000 m., duration, 1 min. 28 sec."

The government of Brazil is planning construction of an airport and emphasis on one of the islands in the harbor of Rio de Janeiro.

The new large Caproni 90 is being prepared for strength on several flights. The Caproni 100 T light plane struck the Grand Prix for its safety at the Sardinia Aerial Show.

A special flight instructor is said to have been successfully demonstrated at Rio, Lazio, by the aircraft, Captain Sarrac, who was the Chief Pilot of the Italian trophy at 1978.

Airlines from Shanghai to Chengdu, from Nanking to Hankou, and from Shanghai to Yunnan are projected by the Chinese aviation government's Ministry of Communications.

A large airport is being constructed near Tokyo, and is scheduled to be ready for service next August. Equipment will include radio facilities and a navigation station.

Japan Aerial Transportation Co. has purchased a Boeing 747-200 and two Fokker Super-Delft planes for use on its Osaka-Shanghai line. Regular service between Osaka and Osaka, opening three weekly, was scheduled for inauguration Feb. 15.

It has been reported that on Dec. 31, 1979, there were 214 aircraft owned by 196 persons in Mexico.

Compañía Aeronáutica de Transportes carried 1,041 passengers in about 500,000 m. of flying in Mexico during January.

An international tourist and communications exhibition will be held in Poznan, Poland, July 6-Aug. 18.

During December days that 2,058 people were taken on aerial sight-seeing trips over Perth, Australia.

La Compañía Aerea Postal Chile has been formed at Santiago, Chile, to transport passengers and mail.

The Japan Navy, a geared four-engine turboprop model engine, rated 350 hp.

at sea level with gross lift, and 508 hp at 11,000 ft. with supercharger, having an initial diameter of 60.75 in. and rotating 1725 and 1500 R.p.m. respectively, for the two models, has been announced by Armstrong-Whitely Co. of England.

Authorization has been given by the government of Brazil for a visit of the Graf Zeppelin, to this place in April or May, and experimental communication has been established between Brazilian National Telegraph radio station and the system in Hamburg, Germany, to be used for weather reports.

Aviation at Zanzibar, Agwa Lufthansa, and Tullahoma, Mexico, have recently been established and opened.

John Munday, of Wright Aeronautical Corp., has been conducting a series of lectures at Embury Grammar School of civil aviation, Moscow City.

Dr. Henry Reptier has accepted the post of technical advisor to a group of English business men who are forming a new aviation company. It is said that \$100,000,000 has been made available for experiment, building a factory, materials, etc.

A special study of instruments used to determine altitude needs is to be made under the auspices of the I.A.I. The company has been prepared to form three grades of altimeters, and it will be submitted at the next meeting.

A Rediffusion House from last week, said during trials was noted after being released for several days, and was to be very light. The material showed no evidence of oxidation, and tests indicated no weakening at the joints.

At Lancaster, Texas, French Air Minister, made a vigorous reply to Socialist attacks recently made in the Chamber of Deputies, charging among other things that he overestimated military aviation.

All of the 150 pilots employed by Deutsche Luft Flotte are taking advanced training in blind flight.

Concerning 2043 on Jan. 18, it was 20 sec., carrying a load of one ton in their German aircraft, German Coates and Jacques Dorel broke the world's records for distance and duration of an airplane.

Proposed from the first month of operation of an air mail service in Guatemala were \$4,216,775, of which \$1,267,180 was paid to the American Airways, Inc.

The Vnukovo and Vnukovo de Shchast are planning an extended tour of Egypt and Africa in a De Havilland Mark. Mrs. Lou Lufthansa and Schmitt are planning a long trip toward Alanya on a Fokker color plane with Hispano-Suiza 230 hp. engine. M. Vnukovo de Shchast is now at La Roche-Rouge last year, is expected to fly to central Africa with his wife.

Qualitative design for value of each model in the Douglas airport in 1979 are 1,413,271,228 francs (\$102,847,600) for imports and 248,182,000 francs (\$12,352,180) for export.

SPRING — SUMMER — SEAPLANES

EDO FLOATS ARE READY NOW!

8 of the 11 standardized models

EDO greets the greatest seaplane year with the largest and most complete stock of floats in EDO history.

With the spring season so near at hand, airplane manufacturers, distributors and transport operators are turning their attention to the additional sales and greater range of service which EDO floats make possible. In view of the tremendous and growing demand for floats, the advantages of this preparedness are obvious.

Standardized in 11 models for the conversion of more than 40 distinct types of landplanes up to 8,250 lbs. gross weight, EDO floats fully comply with U. S. Department of Commerce regulations. They can be quickly interchanged with standard types of wheel landing gear. The close cooperation between EDO designers and the engineering staffs of most airplane manufacturers assures correct and efficient design with the added durability of EDO craftsmanship.

Other manufacturers who seek a wider sales outlet for their aircraft are invited to make use of EDO experience and ability—to build profits

through the EDO Sales Plan which assures complete protection. There is still ample time to enter the 1930 market with a float installation designed by EDO particularly for your machine.

NOW is the time to place an order for the 1930 season, for even your estimated maximum requirement may fall far short of actual demands. Delays of peak season production are avoided and "ready-to-install" is a sales point that will surely put profits at your command. For information address EDO AIRCRAFT CORPORATION, 600 Second Street, College Point, L. I., N. Y.

For Good Castings— Specify Brown & Sharpe

Manufacturers of units requiring air cooled cylinders or other parts can be assured of castings with unusual uniformity—by specifying Brown & Sharpe.

The experience accumulated through the years this foundry has been producing air cooled cylinder castings, is available to solve your problems. Our service is backed by an organization of workmen skilled in work of this character.

BROWN & SHARPE
BROWN & SHARPE MFG. CO.  PROVIDENCE, R. I., U. S. A.

A SPECTACULAR SUCCESS

TEXACO MARFAK GREASE has proved a spectacular success in the field of aviation. It has finally solved the problem of effective lubrication for enclosed rocker arm and valve assemblies, and is equally the ideal lubricant for grease packed magnets bearings and other enclosed parts. A prominent pilots who have tried Texaco Marfak Grease on record-breaking flights testify to its unparalleled lasting qualities and resistance to high temperatures. While comparatively new to aviation, its effective work under many other important and difficult lubricating conditions is a long established fact. A Texaco Marfak Grease—and Texaco Airplane Oil and Aviation Gasoline—are available at most of the important airports of the country. These well-known products offer the highest type of dependable service. Write for the December, 1929, issue of "Lubrication"—devoted entirely to Aircraft Engine Operation.

COLONIAL GRAIN AVIATION LEATHER

This upholstery leather is
lighter than you think

Colonial Grain Aviation Leather is manufactured from the top grain or top cut of the hide. This not only means that the quality is best but that the leather is of real light weight. This leather, therefore, because of its light weight and long wearing qualities, is ideal for Aviation upholstery.

If you will send for a sample you will find the weight much lighter than you now think it is. It does not run over 0.098 pounds per square foot.

THE acceleration is taken care of by a pump with special features so that it gives a prolonged discharge. Further it automatically releases when the throttle is opened and closed too quickly thus preventing "over pumping." Finally the fuel discharges into the center of the air stream.

Descriptive literature, plans for the making, gives full details of design, construction, control and adjustments.

Write today

HOLLEY CARBURETOR COMPANY
Detroit, Michigan. . . . Read
your engine
temperature
DIRECT

THE actual temperature of an air-cooled engine is not the temperature of the lubricating oil. Unlike the conditions in a liquid-cooled engine, heating or cooling may take place at a dangerous rate without a corresponding response of oil-temperature instruments. Therefore, the G-E engine-temperature indicator has an important function, for it measures accurately and instantaneously the temperature of any "hot spot" such as a cylinder wall or head. It consists of an indicating instrument connected by leads to a special washer used as a quick-plug gasket or to small copper-bushed studs, if desired. This instrument is extremely accurate and reliable; it requires no battery, it is not connected to the ignition system.

This heat control is your oil

. . . . heat your oil
ELECTRICALLY

Every engine should be equipped with one or more G-E oil immersion heaters. This device is for connection to any standard electric-lighting circuit. Placed in the oil tank at your engine, it heats the oil properly and facilitates a safe, quick start.

For complete information, address General Electric Company, Schenectady, N. Y.—manufacturer of lighting equipment, instruments for navigation and flight, engine accessories, and ready dealer for the aeronautic industry.

BADGER'S NON-FREEZE FIRE ENGINE

THE only approved 40 gallon Fire Engine that will work when the temperature is below freezing. Gives positive fire protection at temperatures of 40° below zero or lower, in an hour's winter heat. Cold can't freeze or clog it. Leave it in an unheated shed or hangar all winter—even on the flying field! A single lever starts the steam, regardless of temperature. A big volume of liquid under high pressure quickly puts out any ordinary fire before it gets dangerous.

This is the only 40 gal. non-freeze engine which has passed the tests of the Underwriters Laboratories and Factory Mutuals—the only such engine which is recommended by them for use. It offers positive, year-round fire protection that can't be duplicated. Let us send you this whole story.

We offer fire protection for every kind, 40 gal. engine and 21 gal. hand extinguishers in Non-Freeze, Foam, and Soda Acid types, also 1 and 1½ quart Carbon Tetrachloride hand extinguishers.

WHITTELSEY AVIAN... \$3845
DOWN PAYMENT, about... \$1358
Balance monthly payments.
HANDLEY PAGE WING SLOTS
(extra) \$450

All prices F. O. B. Indianapolis, Conn.

IN the short space of one year since its arrival in America, the famous Avian has been accepted by the great part of the American public as representing the measure of safety in the air.

At the International Aircraft Show, just concluded, in St. Louis, the Whittelsey Manufacturing Company presented the 1930 Avian with all its well known safety features plus a refinement of detail and quality of equipment well in advance of common practice.

And we announce at this time a reduction in price, based on quantity manufacture, coupled with a time payment plan which immediately makes the ownership of an Avian a highly practical investment for business or sport.

Here is downright safe performance that no other light plane can equal. And economy that can't be beaten—the Avian makes every gallon of gas give 20 miles of travel. You can now buy an Avian for about \$1358.00 down and balance in monthly payments. Write today for full information on the plane that's built for sport, safety and economy.

To Dealers and Distributors

When you go to sell the Whittelsey Avian you have something to talk about. No other light plane has such a record of performance... as the equipment... and the structure are still being appointed. Write for our sales plan and for full data and specifications of the plane itself. The Whittelsey Manufacturing Company, 125 Howard Avenue, Indianapolis, Conn.

THE OUTSTANDING SPORT AND TRAINING PLANE OF THE WORLD

Glenn L. Martin Co.
The Glenn L. Martin Co.
is a well known
aircraft company.

*A dream
is becoming a reality—*

ON the outskirts of Baltimore an army of workmen are busy erecting an aviation center unique in aeronautics history. On a single, unbroken tract ideally suited to the purpose will be concentrated the new plant and laboratories of The Glenn L. Martin Company, together with a landing field of exceptional character, a harbor for seaplanes and—ultimately—an aeronautical school, a home-community for air-wise aptitudes, and a

hotel for transient visitors. Two and a half million dollars is being invested in immediate construction.

The Glenn L. Martin Co.

Builder of Quaker Aircraft since 1919
BALTIMORE, MARYLAND

THE WRIGHT-GIPSY IS NOW IN FULL PRODUCTION!

THE first automobiles rolled out of the few richest homes in the land. But small dependable motors and mass production sent costs tumbling to where the many could operate cars of their own.

The announcement of the 90 horsepower Wright-Gipsy is, then, an event important to Aviation and to America! For this light, compact and thoroughly tested engine opens new horizons as to who can own and fly an airplane.

The Wright-Gipsy is not a new engine. It is the American model of the famous British de Havilland motor. In Europe, in Asia, in Africa, record after record, success after success, has been marked to the credit of this marvellous light power plant.

It has covered millions of miles . . . it has proven itself safe and easy to fly . . . it is, among motors of its class, a champion already crowned! Built now under Wright precision methods, it has exceeded all government requirements, with plenty to spare.

Pilots of light sport and training planes will find in the Wright-Gipsy, plenty of dependable power, economical cost of operation, and an extreme simplicity of design that makes service costs negligible.
